The demand for trained Electricians is immense. Fine positions are everywhere. Experts must be MADE—to fill them. This situation offers you the best chance you'll ever get to forge ahead QUICKLY in this greatest of all professions.

**Earn $2500 to $8000 a Year!**

QUALIFY for a splendid career through my course. It is simplified to the point of perfection. You'll enjoy it. I and my assistant engineers have worked to make it the most exact, simple, comprehensive and interesting course in America. To show you how PRACTICAL it is—and PROVE you can learn Electricity with SPEED and EASE, I will send you proof lessons—FREE OF CHARGE.

Let a Practical Engineer Personally Train You at Home

**YOU CAN DO THIS**

**AFTER HOME STUDY**

$36.00 TO $100.00 A WEEK

Proof Lessons—FREE!—Free Electrical Outfit!

Act quick and secure a big reduction in cost of tuition. If I hear from you at once I will send you the Proof Lessons FREE, and I will also give you a big outfit of Standard size electrical tools, materials, etc., absolutely FREE. Many other valuable benefits too numerous to mention. Send Coupon NOW—for full details. Don't fail—only a practical engineer can teach you the things you MUST know to succeed big—and as Chief Engineer of the Chicago Engineering Works, I am in a position to help you immensely. Send coupon or write today sure!

**MAIL THIS COUPON**

Dept. 25
CHIEF ENGINEER, Chicago Engineering Works,
441 Cass St., Chicago, Illinois.

Without obligation on my part kindly send at once, fully prepaid, particulars of your complete Practical Home Study Course in Electricity.

Name .....................................................
Address ..................................................
Town .................................................... State .............................

L. L. COOKE
The well-known consulting and advisory engineer, formerly member of Engineering Staffs at American Bridge Co., Pressed Steel Car Co., and Millikan Bros., great international engineers, in New York, London and So. Africa.

I will give you the practical training you need—AT HOME. I will PERSONALLY train you in a WORKING knowledge of Electricity in your SPARE TIME. And I am so sure you will make a splendid success in the study of this fascinating profession—that I will give you a GUARANTEE BOND to refund the full tuition cost to you, if you are not entirely satisfied when you receive your DIPLOMA and Electrician's Certificate.

**CHIEF ENGINEER COOKE**

Chicago Engineering Works
DEPT. 25
441 Cass Street Chicago, Ill.
$5.

The "Boy's Electric Toys" contains enough material to make and complete over twenty-five different electrical apparatus without any other tools, except a seven-diamond finished with the outfit. The box contains the following complete instruments and apparatus which are already assembled:

- Student's chromic plunge battery, compass-galvanometer, solenoid telephone receiver, electric lamp, enough various parts, wire, etc., are furnished to make the following apparatus:

  Electroemagnet, electric cannon magnetic pictures, dancing spiral, electric hammer, galvanometer, voltmeter, hook for telephone receiver, nonconductor, sensitive microphone, short distance wireless telephone, test storage battery, shaking coil, complete telegraph set, electric vibrating machine, electric buzzer, dancing fish, singing telephone, mysterious dancing man, electric jumping jack, magnetic geometric figures, rhesostat, erratic pendulum, electric battery, thermon electric motor, visual telegraph, etc., etc.

This does not by any means exhaust the list, but a great many more apparatus can be built actually and economically.

With the instruction book which we furnish, one hundred experiments that can be made with this outfit are listed, nearly all of these being illustrated with superb illustrations. No other materials, tools or supplies are necessary to perform any of the one hundred experiments or to make any of the 25 apparatus. Everything can be constructed and accomplished by means of this outfit; two hands, and a screwdriver.

The outfit contains 114 separate pieces of material and 24 pieces of finished articles ready to use at once.

Among the finished material the following parts are included: Chromic salts for battery, lamp socket, bottle of mercury, copper wire (two different gauges), a bottle of iron filings, three spools of wire, carbon, a quantity of machine screws, flexible cord, two wood bases, glass plate, paraffine paper, binding posts, screw-driver, etc., etc. The instruction book is so clear that anyone can make the apparatus without trouble, and besides a section of the instruction book is taken up with the fundamentals of electricity to acquaint the layman with all important facts in electricity in a simple manner.

We guarantee satisfaction.

The size of the box is 14 x 9 x 3 1/2. Shipping weight, 8 lbs.

No. EX2002 'The Boy's Electric Toys' is illustrated as described...

ELECTRO IMPORTING CO., 231 Fulton St., New York

The "Electro" Radiotone
High Frequency Silent Test BUZZER

This instrument gives a wonderful high pitched MUSICAL NOTE in the receiver, enabling anyone to test ordinary test buzzer. The RADIOTONE will surely appeal to the interests of the average amateur and in most cases, can be set up in the receiver. The instrument consists of a single filament, with an adjustable high speed, and a most efficient transformer for thefaculty. To learn the code, there absolutely nothing like it. With the radiotone key and one or more tests, you can soon make sharp in your apparatus. To learn the code, there absolutely nothing like it. With the radiotone key and one or more tests, you can soon make sharp in your apparatus.

Price Complete as illustrated TWO INSTRUMENTS...

The "Electro" Telegraph

is not a toy, but a practical, honestly built telegraph outfit that will do everything that a telegraph outfit is supposed to do. The parts are no better and more complete than the box, and although it is quite expensive, it is designed for the amateur who wants a complete and practical telegraph. The "Electro" is the only outfit that works both ways, and can be used for telegraphy and telephony.

Price Complete as illustrated TWO INSTRUMENTS...

Electro IMPORTING COMPANY, 231 Fulton St., New York City

I enclose herewith 6 cents in stamps or coins for handling and mailing this catalog of our latest CYCLOPEDIA Catalog No. 19, as described.

NAME... ADDRESS... STATE... 

May, 1918 ELECTRICAL EXPERIMENTER
AVIATION MECHANICS

Needed for New Positions

Thousands of splendid new positions now opening up everywhere in this amazing new field. New Airplane factories being built—automobile and other plants in all parts of the country being converted to turn out vast fleets of Airplanes for our armies in Europe. And only a few hundred expert Airplane Mechanics available, although thousands are needed. And this is only the beginning. Already airplane mail routes are being planned for after the war and thousands upon thousands of flying machines will be wanted for express and passenger carrying service.

Not in a hundred years has any field of endeavor held out such wonderful chances to young men as are offered to you today in the Aviation Industry. Resolve now to change your poorly paid job for a big paying position with a brilliant future. Send the coupon today for Special limited offer in Practical Aeronautics and the Science of Aviation and prepare yourself in a few short months to double or treble your present salary.

We Teach You By Mail

IN YOUR SPARE TIME AT HOME

Our new, scientific Course has the endorsement of airplane manufacturers, aeronautical experts, aviators and leading aero clubs. Every Lesson, Lecture, Blue-Print and Bulletin is self-explanatory. You can fail to learn. No book study. No schooling required. Lessons are written in non-technical, easy-to-understand language. You'll not have the slightest difficulty in mastering them. The Course is absolutely authoritative and right down to the minute in every respect. Covers the entire field of Practical Aeronautics and just the kind of practical training you must have in order to succeed in this wonderful industry.

Special Offer NOW!

SEND THIS COUPON TODAY

It is our duty to help in every possible way to supply the urgent need for graduates of this great school. We have facilities for teaching a few more students, and to secure them quickly we are making a remarkable Special Offer which will be withdrawn without notice. Write today—or send the coupon—for full particulars. Don't risk delay. Do it now.

AMERICAN SCHOOL OF AVIATION

431 S. Dearborn Street

Dept. 7445 CHICAGO, ILL.
WINNING THE WAR

By H. Gernsback

His war, more so than any other, is a machine war. A stereotyped phrase, but, nevertheless, a very true one. When we speak of a machine war, we usually have in mind artillery of all calibres, from machine guns upwards to 42 cm. guns, and larger.

We believe that we will not be contradicted when we state that vast bodies of infantry cannot move forward nowadays without the support of protecting artillery from its rear. Logically, the conclusion follows, that if we can annihilate the enemy's artillery, he must fall back. Even trench systems without artillery support from the rear cannot be held for any length of time by the enemy. If our artillery is intact, but if the enemy is deprived of his, even tho his infantry should outnumber ours ten to one, he would have to retreat just the same. These, of course, are very obvious facts.

The British now engaged in the Western war theater realized this truth very early and set about to rectify it. The result was their present Tanks. These machines fulfill several purposes; they are used to batter down the barbed wire entanglements protecting front line trenches; secondly, they raise havoc among the enemy's men by flank fire once its lines are crossed; thirdly, the important thing is that all the Tans are supposed to annihilate the enemy's artillery either by putting the artilleryists out of the game from the rear or by driving right over the enemy's guns, thus putting them hors de combat. For the first two purposes the Tanks are ideal, for the latter they have signally failed. The reason is very simple. The Tank is an extremely slow-moving vehicle in the open field—five to eight miles an hour at the most is its speed. Even if camouflaged, a Tank makes a shining mark for the enemy gunners, who find little trouble in getting the range of it. A rapid-moving tractor. One or two shells soon puts the most ambitious Tank out of business.

Dr. S. C. Pike, in his book, has made it appear that we have not only in our cities but also in our factories and workshops, the raw material for Tank production. As a matter of fact, what we need is not only steel, but also the necessary power to produce this steel. Even if we could build the steel, we would have to import the coal necessary to produce it. And we have also to import the required for them. And we have also to import the iron ore needed to produce the steel.

In other words, the large and speedy machine obviously is the 'thing' in this war. In former articles we have shown that it is perfectly feasible to run monster machines over land at speeds from twenty miles upward. We have shown how our obsolete battleships could be readily equipped with huge channel-iron wheels to ride over land; we have also shown how 45-foot big-wheel steel monsters, steered by gyroscopic means, could be used to run over the enemy's artillery. And we have also shown how these machines could be practically immune to enemy shell fire on account of their high speed. The conditions of action are likely to be largely open iron-channel work, even a direct shell hit would not do much damage, beyond ripping out a few steel pieces.

Strange to say, monsters of this kind would claim little to life: if you see such a juggernaut of death heading your way, you simply sidestep it! Such machines are not designed to kill; they are used solely to destroy the enemy's guns, or putting them out of action.

Now the point we wish to make is that men alone will not win the war for us. A big machine is the thing. One such monster replaces several thousand men. The nation that can build the largest buildings on the Earth that has the largest mechanical resources of the Allies, can easily build these comparatively simple machines. They are feasible from an engineering standpoint. Most important of all, such machines can be readily sent to France and within a couple of hundred of them could be sent to France with the same amount of tonnage it takes to send over 25,000 of our boys. Five hundred big monsters might decide the war for us quickly: 25,000 men are a mere trifle in this war—they do not begin to make an impression.

A few weeks ago, if we had proposed a gun that could shoot 24 miles we would have been laughed at scornfully. It would have been one of our 'pipe dreams.' The trouble with us Americans is that we don't 'dream' enough, while the Germans do.

And if we do not get the big machines over to France soon, the Germans will surely beat us to it. Let us wake up.
The only way you can become an expert is by doing the very work under competent instructors, which you will be called upon to do later on. In other words, learn by doing. That is the method of the New York Electrical School.

Five minutes of actual practice properly directed is worth more to a man than years and years of book study. Indeed, Actual Practice is the only training of value, and graduates of New York Electrical School have proved themselves to be the only men that are fully qualified to satisfy EVERY demand of the Electrical Profession.

At this "Learn by Doing" School a man acquires the art of Electrical Drafting; the best business method and experience in Electrical Contracting, together with the skill to install, operate and maintain all systems for producing, transmitting and using electricity. A school for Old and Young. Individual instruction.

No previous knowledge of electricity, mechanics or mathematics is necessary to take this electrical course. You can begin the course now and by steady application prepare yourself in a short time. You will be taught by practical electrical experts with actual apparatus, under actual conditions. 5,000 of our students are today successful Electrical Practitioners. Come in and read their enthusiastic letters. Let us explain this course to you in person. If you can’t call, send now for 64-page book—it’s FREE to you. SCHOOL OPEN ALL SUMMER.
Electricity and Camera Give 3,000,000 Shells Third Degree

Have you ever stopped to think just how the experts of the ordnance department of our own as well as foreign governments manage to check up the huge quantities of cannon shells shipped to the front? Possibly not, when the accompanying photos will give some idea of the extremely fine electrical precision apparatus employed for the purpose, as well as the method used for safely firing faulty shells.

The photo at left illustrates the delicate electric chronograph, a highly sensitive and electrically operated camera, the whole lot of 25,000 shells was immediately returned to the manufacturer.

The electric chronographs or split-second clocks used in timing the velocity of the shells when fired, are connected up to a network of electric wires placed at certain predetermined intervals along the proving range. Briefly explained the operation of the velocity test is as follows: As the bullet or shell leaves the muzzle of the gun it strikes one net-work of electric wires, severing one of the wires, which causes one for exploding shells that have failed to go off when fired. The shells are recovered by "shell scouts" on the range and are fired off electrically by the officer in charge.

Photography played an important part in testing the 3,000,000 Russian shells at the Lakehurst proving grounds. It is said to be the first time that the electric camera was ever used in this country to determine the velocity of projectiles.

Right photo shows five of these remarkable instantaneous photos of shells in flight. These views show shells photo...
Locating and Destroying “Subs” with Electro-Magnets

THERE'S one thing certain about this war anyway, and that is that there will be no falling off in the business of the patent office. Not if the Yankee inventors can help it, at any rate. For one thing they will be able to keep the patent examiners busy on anti-submarine devices for several years to come, apparently. We thought that the magnet schemes for combating the U-boat menace were about exhausted—we said "thought," but here's a new one. And it employs electro-magnets—oodles of them if necessary. The inventor of this newest magnetic "Sub" thru the danger zone, so that a large area may be covered in a predetermined time. A substantial base is secured rigidly upon the aft deck of the vessel as shown in the illustration herewith. This base preferably extends beyond the line of the hull, as it is upon this base that most of the working parts of the device are mounted.

Pivoted at the rear end of the base is a rearwardly projecting, vertically swinging boom which is by preference extensible and retractable, set screws or clamps being provided for holding it in adjusted position. The rear end of the boom is forked as at any suitable point on the ship, a generator being provided for charging the battery to the required extent. The generator may either be driven from the internal mechanism of the ship, or from an individual motor or engine.

The two cables attached to the electro-magnet are wound upon a drum suitably mounted upon the deck base, the anchored ends of the duplex electric feed cable, being past thru the hollow shaft of the drum and secured to a pair of contact rings which are insulated from the shaft, that is the two wires which comprise the feed cable, are..
Yankee Code Not So “Bloedsinnig”

With the American Expeditionary Army, France.—’T’ll be in Oregon at 3. At 4 o’clock I’ll be fixing up that ration question with Hindenburg in London. And if you want me after that I’ll be over in Tallahassee. Just ask for the Kaiser.”

Not a quotation from the raving of a mad man—nor “balmy in the ead,” as our British friends are wont to call the chap who is a bit “locol” in his “attic.”

The foregoing conversation is just one end of a typical ‘phone talk on the front where everything is “code.”

The young divisional supply officer was about to leave on a round of the fighting points on the front. He was giving one of his subordinates instructions over the phone on how to reach him in case of need during the remainder of the afternoon.

“Oregon” is an artillery post a few kilometers from headquarters—not the Western State where the apples come from, Hindenburg is a battalion commander whose right name may be Smith, and London is a dugout in the support line “up front.” After that he was going to a brigade headquarters. On the phone he answers to the name of “The Kaiser.”

It’s simple if you have the key, but a crazy confusion of far-flung places and irreconcilable names if you don’t know what they’re talking about.

This “code” is a safeguard against enemy “listening-in” sets. By means of induction—stringing wires parallel to our trenches, tho 50 yards away in “No Man’s Land”—the sly Germans often pick up the Yankee talk over the wires. It therefore becomes plain that if a Boche listening post picked up that message the observer scanned his maps of the sector in vain for “London” and “Tallahassee.” And “Hindenburg”—there’s only one Hindenburg and he isn’t visiting London these days to consult on rationing problems. Every loyal Boche knows that. The “bloedsinnige” (idiotic) Yankees must be mad.

It is an interesting fact that where tele-distance circuits when they happened to be parallel one another for any appreciable distance. Inductive effects were manifested between the telephone cables leading from New York City to Saratoga, N. Y., and Providence, R. I., due to the proximity of these two circuits in New York City.

Every insert detail here shown gives the simple arrangement necessary for listening in by induction to conversations in a certain telephone line. The listening post of the enemy may moreover be equiped with powerful amplifiers to intensify whatever messages are intercepted. Ordinarily it is only necessary to connect up a telephone receiver to the single “paralleling” wire.

This is usually a simple matter, as the trenches frequently run nearly parallel for considerable distances. The listening wire should, of course, be insulated and part of it might be camouflaged or hidden in the dirt of “No Man’s Land,” so as to reduce the distance between the two circuits, and thus increasing the inductive effect. In some instances the telephone lines have been but a few feet apart.

An early American radio-worker, one Amos E. Dolbear, invented and patented an inductive telephone and telegraph system and actually made it “talk” one-half mile. His patent was issued in 1888, but owing to the limitations of such a system (Continued on page 66)
New Spy and Scientific Movies
By GEORGE HOLMES

There seems to be no dearth of interesting photoplays, especially among those that depend on science to attract theater patrons. One film-play in particular is very much in the limelight at present, being the exposé of numerous plots against the United States even before we were drawn into this great world conflict.

Written by that celebrated authority, Wm. J. Flynn, late retired chief of the U. S. Secret Service, the drama under the title of "The Aquarium" has just been captured by a band of German spies and taken to their headquarters in an abandoned cave on the New England coast, where they propose to force her to reveal the secret of a marvelous war invention perfected by a lieutenant in the United States Army. Jessie pretends to faint and while her guard rushes for aid she makes her way to the wireless instru-

to get money to complete her father's scientific researches, marries a wealthy man she doesn't love. A son is born to the couple only to become a barrier between them. The husband leaves for a long sea trip, is reported lost, but turns up at home just in time to see Laurel promise herself to Richard Leslie, a young doctor she had loved before her marriage. The death of their son embitters Durand, the husband, and he plans a revenge as fiendish as it is novel.

*The Eagle's Eye* leads one thru a series of episodes which show the despicable methods and plots originated to wreak vengeance and hamper as much as possible the war effort of the "Hun"!

Two of the photos show a specially built wireless-controlled torpedo which the Imperial German Government made in this country for the destruction of the flagship of the Atlantic Fleet as it was leaving New York Harbor after the review of U. S. Navy. Also there may be seen a compact land radio set tuned with the apparatus on the torpedo, so that perfect control may be had.

He pretends a deep interest in the young doctor, and thru various pretext throws the pair together on every conceivable occasion. Laurel finally discovers a serum for the cure of the deadly anthrax germ thru the medium of the man-eating turtle. She possesses but one small specimen of the turtle, the only other one being the property of the city Zoo. Supremely confident of the serum, she decides to demonstrate the efficacy of her cure for anthrax by inoculating herself with the deadly poison. Young Leslie begs her to use him (Continued on page 66.)
ELECTRICITY at high potentials has been used heretofore in an effort to stimulate the germination and growth of plant life, particularly those of a food-bearing nature. Several English experimental farms have been trying out such schemes with more or less success, but apparently the method used whereby several hundred thousand volts of high frequency current is caused to "leak off" an elevated wire net-work to the plants themselves, left considerable room for improvement.

This improvement seems to have been made by a Chicago, Ill., genius, Mr. Robert D. McCreery, who has provided a truly novel scheme whereby the high potential, high frequency currents do not have to traverse several million ohms of "air resistance" before reaching the plants, but are enabled to pass thru the earth directly to the roots of the growing plants or to the seeds undergoing the process of germination. An increase of 30 per cent and more was attained in the crop production as proved by actual "growing" tests.

"Electricity," declares Mr. McCreery, "unquestionably stimulates seed germination and subsequent plant growth. Electricity in the soil causes larger crops and healthier plant life. With the end in view of stimulating food crops in England at a time when the submarine menace was the gravest, the Government devised the plan of stringing wires across the fields and causing them constantly to disseminate an electric current.

"Undoubtedly more electricity is lost in the air than is brought into contact with roots of the growing crops. The new system aims to eliminate this waste. By employing it the electricity is diffused directly into the ground, where it is brought into contact with the metallic element covering the seeds. High frequency electricity always seeks out the points of lowest resistance. These are my metal coated seeds. "Electrodes are set at the opposite ends of the field or garden plot and electrically charged. They serve to spray electricity thru the ground devoted to the growing of the crop to be so treated. In order that the juice may reach its proper objective the seeds or shoots are surrounded with a metallic element. With ordinary seeds this can be done in large quantities and in a very few minutes. Indeed, the process is so simple that a farmer's lad operating it can coat enough seed corn in ten minutes for planting twenty acres of corn.

"The control of the electricity is brought about by metallically coating the seed with a finely divided non-deteriorating metal before planting, thus creating lines of low resistance, since high frequency waves are automatically drawn to anything metallic. (See detailed drawings in illustration herewith.)"

"After the germination of the seed—which is both hastened and assured by the electrical treatment—this metallic element continues to inhere in the roots of the plant and absorb more current, thus establishing a continuity of the system."

The idea of metalically coating the seed does not debar its use for such garden products as are grown from sprouts or from portions of the parent plant, as is the case with potatoes, celery, etc. McCreery declares that the electrical treatment will be wonderfully effective in growing garden truck.

"Where the electric system is used," he explains, "it is necessary that the individual plants have the metallic element previously alluded to. But this need not be a part of the seed itself. In fact, for certain plants it is just as well that the ground immediately around them be impregnated with the metallic property. (See illustrations.)"
The Electro-Magnet in the Operating Room

By S. Gernsback

In a modern war hospital, the electro-magnet is playing a big rôle nowadays. It is practically impossible to thoroughly clean wounds of shrapnel splinters without the use of this practical apparatus, as in many cases these particles are included by the dozens in the human body and it would be a great loss of time to the surgeon as well as pain to the patient, if each fragment had to be located and extracted separately.

When the wounded soldier is brought to a base hospital, all the big iron fragments are easily located, and are removed by hand and forceps. After this first operation a thorough search for small splinters is made, with the aid of a strong electro-magnet.

But that the electro-magnet should be in every hospital, ready to be used at any moment, is shown by the accompanying illustrations.

Some time ago a young boy was brought to a hospital in New York City on account of a swelling of the knee and excruciating pains in the same.

An X-ray examination showed that the patient had a phonograph needle imbedded deeply in his knee.

The needle must have worked itself into the patient’s knee, a boy three years of age, while creeping on the floor. It was decided to remove the needle by an operation.

Altho there was a front and side view X-ray taken, to ascertain the exact location of the needle, the surgeons at the beginning of the operation could not find the object and finally called for an electro-magnet.

After applying the current, the magnet was brought in the incision made by the surgeons in the patient’s knee and the phonograph needle was extracted at once and clung to the pole piece of the magnet.

DENTISTS TEST NERVES NOW BY ELECTRICITY.

It frequently happens that the nerve of a tooth dies, even when the tooth is apparently sound, without giving any external indication. This almost universally results in an abscess in the bone structure at the end of the root of the tooth, which abscess may not give any local pain or external indication of its presence and may exist unknown for years. During this time the pus continuously formed in the abscess is absorbed into the system and may cause various ailments, such as rheumatism, heart disease, kidney disease, etc., all really due to the pus carried by this dead tooth nerve but often attributable to other causes. The dentist may have examined the tooth many times during this period and found nothing wrong, because of the absence of any external signs.

It is the object of the invention here illustrated to provide an electric nerve-testing instrument, by which the dentist may determine absolutely whether or not the nerve of a tooth is vital. It was invented and patented by Mr. Arthur R. Darling, of Indianapolis, Ind. The instrument is provided with a probe of conducting material of suitable form to engage the tooth, and this probe has associated with it an induction coil with a variable-reluctance magnetic circuit, interconnecting the primary and secondary coils. When the dentist presses on the center rod as shown, the induction coil core is pushed in and the reluctance reduced, thereby increasing the voltage of the secondary winding of the induction coil. The secondary of this induction coil has one terminal connected to the probe and the other provided with any suitable connection whereby the secondary circuit thru the tooth may be completed, as thru the dentist’s hand, which is placed in contact with the patient’s face or neck. Preferably the make and break device for this induction coil is separate from the instrument, to avoid vibration in the instrument.

In testing the teeth the dentist grasps the instrument in the manner shown, pushing down slowly on the center core plunger which raises the secondary voltage, and hence the strength of current applied to the tooth and nerve. If the nerve is dead, the dentist can push the central core rod entirely into the spool and the patient will feel nothing in the tooth being tested. If the nerve is vital, the patient feels the current in the tooth before the rod has been pushed in very far. A whole set of teeth may be tested in a few minutes.

COST OF ELECTRIC PIG IRON.

Based on experiments at Trolhättan, 4 tons of pig iron should be produced per kilowatt-year in a plant using only one furnace, measuring the energy at the furnace, says The Engineer. Figured on the amount of energy purchased, the output should be about 3.32 tons per kilowatt-year. Better results may be expected from a plant of two, or three or four furnaces. With a plant of four furnaces, it is assumed that an efficiency of 92 per cent can be attained, and with two or three furnaces between 83 and 92 per cent respectively.
ENGLISH USE MICROPHONE TO FIND U-BOATS.

Two of the methods by which the British are effectively fighting the German submarine are by the use of new microphone detectors and explosive bombs of enormous power, according to a writer in the Tidningen, an authority on technical information.

English experts have so improved the use of the microphone on anti-submarine vessels, says the writer, that they are able to steer accurately and automatically down on the submarine, while formerly they were unable to locate a vessel beneath the surface. The microphones are placed below the water close to the keel of the vessel, and answer the same purpose as the microphone of a telephone. By listening to the beat of the submarine’s propeller they can determine the exact location of the enemy and attack him before he has the slightest idea of what is happening.

The detection instruments used with the microphones are very complex. One of them shows the distance of the submarine on a graduated scale, the indicator responding electrically to the sound from the submarine’s propellers. The variations of distance are shown with marvelous accuracy. Another device shows whether the enemy is on the port or starboard side. The electromagnetic needle moves to the side on which the sound is loudest and the ship is guided accordingly.

When the proper spot is reached bombs are dropped in the same manner as from airplanes. Their under-water force is so great that they can destroy a submarine 150 feet from the point of explosion.

ELECTRICITY AS A TRENCH DIGGER.

It is reported that the French are making extensive use of electricity at the front in the operation of all kinds of excavating machines. Working in ordinary earth, four men with two wheelbarrows and a machine driven by an electric motor can shift from twenty-five to thirty-five tons a day. In a month a shelter with sleeping accommodation for 500 men can be dug by a single company.

Zip! Goes the Motor and Plaster Cast is Off

The doctors and nurses are right on the job in the present stirring times, when it comes to having electrical devices and refinements. If you think the soldiers and sailors have a mortgage on the "juice" operated inventions with which to push the "Hun" back across the border—well, guess again. Ever see the "Doc" cut a plaster-of-Paris cast loose from a wounded patient? Yes, it was an awkward job at best. But now the electric cast cutter severs the encasement in one clip. It is provided with a special saw over a plate which slips under the cast as slung.

The Medical Corps is doing everything in human power to comfort our injured boys at the front thru the instrumentality of new surgical instruments.

When it is required to repair a part of a broken skull the new motor-driven drilling device here illustrated will bore a hole with accurate precision, so it will not affect the tissues in the head. Such operations are often necessary at the front line and base hospitals, as, for instance, when a soldier has received a heavy blow on the head. This often results in a clot of blood forming which presses on the brain, depriving the victim of some of his faculties at least. In such cases the surgeons must trephine the skull, i.e., cut out a triangular piece of the skull in order to remove the blood clot. Afterwards a silver plate is placed over the opening.

TELEPHONE CONNECTIONS ON THE EASTERN FRONT.

An interesting development in methods of electrical communication between head-quarters and the men in the trenches—namely, the use of wireless to a degree unexpected previous the war is commented upon in the French journal L'Industries Electrique. It was formerly assumed that wireless methods of communication would be unsuitable in such circumstances, owing to the ease with which messages can be intercepted by the enemy. The tendency has therefore been to rely mainly on telephone connection, notwithstanding the ease with which this connection may be ruptured by bombardment. The destructive effect of modern artillery has made the ordinary methods of laying wires along the surface of the ground or attaching them to trees of limited utility. Even buildings and wire-ducts may be destroyed at an inconvenient moment by explosive shells, and the more the depth at which such wires are buried has become continuously greater and the methods of protection more elaborate.

The Germans have sought to get over this difficulty by laying a regular network of interconnected lines, so that in the event of several being damaged there is still a path for the current. Even this precaution, however, may fail in a modern bombardment, and the Germans now appear to be relying to a much greater extent on wireless communication. The article in question quotes particulars which are said to apply to the latest German practice, according to which it would appear that the antenna are mounted 4 meters above the surface, are about 100 meters long and emit waves of 30 to 400 meters. On the Eastern front about 110 wireless detachments are said to be employed.

HIGH FREQUENCY CURRENTS HELP BRAIN TROUBLE.

The case of a model young woman who suffered from a mental aberration is described by Dr. S. St. John Wright in the American Journal of Electrotherapeutics. Some months ago she underwent a mental change, becoming morose, listless, apathetic and strange. On October 4th she declared life not worth living and would kill herself. She jerked her head and fell to the floor, and acted riotously. During a lull in the excitement, they came to me, says the doctor. A severe proctitis was found and treated by glass vacuum electrodes and the high frequency current and resorcin swab. Another slight riot occurred in the afternoon of the same day but none since. After five treatments her muddy countenance rapidly cleared. She is now herself: active, cheerful and delighted, and delighting her mother and step-father. She has resumed her music, correspondence, and domestic activities. All evidence of tenderness and pain had vanished after the second treatment. This case well illustrates the fact that mental aberrations may be due to local focal causes, and that its removal or correction at an early date restores mental equilibrium, and cheats the asylum.
Television and the Telephot

By H. Gernsback

The subject of the present article "Television, or Seeing at a Distance," is one of these inventions. Numerous inventors have busied themselves trying to invent an apparatus or machine whereby it would be possible for one person to see another while talking on the telephone, but so far nothing practical has resulted. The true instrument on which the name "Telephot" (from the Greek tele-tar, photos-light) has been settled, is supposedly an apparatus attachable to our present telephone system, so that when we speak to our distant friend, we may see his likeness not only as an immovable picture, but we will see his image exactly as we see our own image when looking into a mirror. In other words, the apparatus must faithfully follow every movement of our distant friend whether he is only five blocks away or one thousand miles. That such an invention is urgently required is needless to say. Everybody would wish to have such an instrument, and it is safe to say that such a device would revolutionize our present mode of living, just as much as the telephone revolutionized our former standard of living.

Most inventors who had been working in the past on this problem, failed to bear in mind a very important consideration.

If the Telephot is ever to be a success, it must of course be possible to attach it to the present-day telephone lines. That means that the instrument must of necessity work in conjunction with the telephone and the ground for a return "wire," which is the same thing as two wires. Over these two wires to-day, we do not only speak, but "Central" also rings your bell. In the case of a "pay-station" telephone, quite a few more functions are accomplished over these two wires, It is also possible to-day to telegraph or telephone simultaneously over two wires neither one or the other being affected. Why then should it not be possible to also send translated light impulses over the same time that the voice impulses are translated over them?

In most of the schemes offered by inventors heretofore, a plurality of wires was necessary; in some cases several thousand pairs of wires. No matter how well such an instrument might work, this alone would doom it to certain failure. Another point is that the future Telephot must not be a cumbersome machine requiring motors and all kinds of other cumbersome machinery, difficult to operate by the layman.

The future instrument must work the same as the telephone, in that all the subscriber has to do is to lift the receiver off the hook, and he will immediately see his friend just as if he were talking to him in the same room. The requirements may seem hard on the inventor, but they are absolutely necessary as a simple reflection will show.

The writer also ventures to say that no Telephot will ever amount to anything that necessitates the use of selenium. As is well known, in nearly all past suggested television schemes, the selenium cell in one form or another was used. The underlying idea of these schemes is that light rays of the object striking the selenium cell varies the resistance of it. For the same, and these various impulses are then sent over the line to be translated into a picture by various means and manners at the receiving end. The trouble with the selenium cell is that it is not sensitive enough, and on account of its inertia does not work fast enough. Also in most of the proposed television schemes, a multitude of selenium cells is required, which again means a plurality of wires, thereby dooming the scheme at once. There must be something else besides selenium that can translate light impulses into electric impulses. Indeed, such a scheme is already existing, having worked it out millions of years ago. And while it is not electrical, it illustrates what we are driving at.

The animal eye is the most marvelous television apparatus ever invented. Moreover, it is non-electrical, for when we see an object, the latter is thrown into our eye, which is nothing but a marvelously efficient camera, but instead of a photographic plate, the impulses are thrown on the Retina which records the object, not only in black and white as does the
photographic plate, but the picture is recorded in its natural colors on the retina. From here numerous fine nerve strings interlocked in the retina connect with the optical and auditory nerves. This connection with the occipital lobes of the brain, translating the various light impulses, (stimuli) with their component colors into a "picture," which is then "seen" in our mind. We say "seen" advisedly, because of course the picture is not actually seen in the mind, but the impulses which the retina has picked up are translated into another form, which we experience in turn as the sensation of seeing.\* 

As has been shown experimentally, the picture is retained on the retina for about one-tenth of a second, and as an afterimage is a complete proof of the persistence of the image. It is this phenomenon which is made use of in moving pictures, each successive picture staying on the screen for a tenth of a second before the next one is flashed on. The fact that the pictures follow each other so rapidly, gives the impression on the retina that the objects are moving on the screen, which of course they do.

Now, as we have shown that pictures can actually be transmitted at a distance, without the means of selenium cells, it is up to our inventors to devise something to do away with these cells entirely. It is safe to say that when the successful Telephot is finally developed, it will be found to be a very simple apparatus, probably not much more complicated than the present-day telephone receiver.

When one considers how many different functions the diaphragm in a telephone receiver performs, it seems that it should be a simple matter to translate light impulses into electrical impulses. Just stop and consider that a single telephone diaphragm of course can pick up several hundred pure notes as well as several thousand less pure ones, which in turn is translated into electrical impulses. These impulses are then sent over the line only to be re-translated faithfully into the same several thousand notes, which in turn are translated into electrical impulses. These impulses are thus repeated on the line over and over again. But here the telephone loses its usefulness, for no one but the receiving diaphragm at the other end of the line would ever hear anything.

Theainteractive device is therefore the speaker or receiver, and in this, the voice is translated into electrical impulses which are now sent over the line along with the voice impulses. In order that the distant person may see the speaker's face, it is of course necessary that the latter's face be illuminated. For it goes without saying that if the speaker was in the dark, his friend could never possibly see him on the other side because light impulses would be thrown on the "sending" end. For this reason it will be necessary to provide a lamp \( R \) at the top of the Teleplot, which lamp throws its ray on the speaker's face; from here the light rays are thrown onto the lens, theme to be transmitted to the distant station. Naturally goes without saying that the ideal Telephot should transmit the sound and picture simultaneously.

Quite a good many Teleplots have been imagined and described as well as patented in the past. None of these, however, have ever appeared—most of them only existing on paper. One of the first of these was invented by the Frenchman, Dussaud, in 1877. There was another one invented by Sawyer in 1888. Next we have the Biddle machine of 1891; the one of Weiller in 1889; as well as those of Szepanich and that of Dussaud of 1898. None of these, however, were of practical value. We may also mention the comparatively modern Teleplots of Rothschild of 1907; Belin apparatus of 1907; Kruth of 1910; Hoglund of 1912; A. C. and L. S. Anderson of 1912; Stille of 1912; the Rosing apparatus of 1915, and the Sindling-Larsen instrument of 1916. The more important ones among these have been described in this article.

One of the earliest Teleplots imagined by the Frenchman, Dussaud in 1898, is illustrated herewith.

This ingenious apparatus at the sending end has a camera \( A \), at the rear of which is a metal disc \( B \) perforated with certain holes. This disc is driven by clockwork contained in the case \( E \). The ingenious part of this arrangement is that the disc \( B \) is perforated in a curious manner, the holes being disposed in the form of a helix or involute spiral. In other words, when the disc rotates the perforations cut off successive points of the picture formed in the camera \( A \). Thus at each fraction of a second, a ray of light is allowed to fall on the selenium cell \( C \), and when the disc has made one full rotation, every point of the picture will have been uncovered, as will be clear by a little reflection. It is apparent that this is an arrangement which translates light impulses into electrical impulses due to the fact that more or less light reaches the cell. These impulses in turn are passed through a battery and a small transformer (induction coil) \( D \), which is grounded at one end; the other wire goes to the receiving station. At the latter point, we receive more or less intense electrical impulses, and these impulses operate a very sensitive telephone receiver \( T \), on which is hung an opaque plate \( E \), having fine transparent lines engraved on its face.

Electrically Heated Beds for the Wounded

Once it was thought that a patient was receiving the finest kind of treatment if he was surrounded by hot-water bottles, i.e., providing he required that kind of treatment. Now the English hospital experts have devised an electrically heated mattress for treating such cases as pneumonia and shell shock. The hot water bottle provides an uneven heat at best—and for the proper treatment of such cases as these, the heating effect must be uniform and should be capable of fine regulation.

A successful solution has now been reached by Mr. H. J. Gauvain at the Treloar Cripples' Hospital, Alton, England, where two wards are now supplied with electric mattresses which have proved both safe and convenient in practise even when a child is the occupant of the bed.

The mattress does not differ in appearance from any other except that a flexible wire enters it at the head end thru a terminal which is flush with the surface, and therefore not exposed to injury. The resistance wire is insulated by glass beads in flexible metallic tubing incorporated in the substance of the mattress. The mattress is differentially heated and the heating element is so disposed that the maximum warmth is generated at the foot-end, less in the middle, and none at all at the head end. This distribution of heat is maintained in whatever position the mattress is turned, either from head to foot or side to side.

The wires are connected with a switchboard on the wall at the head of a bed which contains a variable resistance, so that the current can be graduated to any required extent. It is so arranged that when the current is full on the temperature of the bed is raised 25° to 30° F. above that which would obtain apart from the heating, and this has been found in practise to meet the needs of the small cripples, many of whom are fastened on splints which do not allow of the close contact of the bedclothes. A fuse prevents the passage of any current exceeding this amount.

Several of the usual difficulties have thus been met: the temperature of the mattress can not rise to any dangerous degree, the and infirmaries would save much time and relieve the nursing staff of a tiresome routine. Electrically heated beds have already been found of advantage in the treatment of shell shock at field-hospitals, and for military purposes it will be seen that the current required may be instantly supplied from a portable dynamo driven by a motor-lorry or car, as shown in the accompanying illustration.

Germans Building Aluminum Transformers.

Scarcity of copper has led to the construction of transformers with aluminum windings, says a German writer, and he contends that it is possible even in normal times to build air-cooled transformers cheaper and lighter if aluminum be employed instead of copper. The ratio of the prices of insulated aluminum and copper wire is taken as 1.4:1.0. In the most economical design of transformer with copper windings it is necessary to leave considerable spaces between the coils in order to obtain adequate cooling. When aluminum windings are used this space can be conveniently reduced without prejudice to the temperature rise. Owing to the relatively greater proportion of the cross-section of the coils which is occupied by metal, the difference between internal and external temperatures is less with aluminum windings than with copper. The difficulty of making joints in the winding is rather serious.
POSSIBLY many readers have seen, or rather heard, loud-talking telephones in operation as the latter's sphere of usefulness is being extended daily. They are being used very successfully for announcing trains in railroad terminals and have been used for several years now in announcing plays from the fronts of theaters in the larger cities, such as New York, and they have also found considerable adoption in railroad train despatching, as well as in a number of other fields.

The writer, while recently riding on a subway train, thought of the idea of combining these successful and practical loud-talking telephones with a phonograph attachment, which arrangement would seem to fill a great many requirements in public places, such as in subway and elevated trains, on steamships, in department stores, for store window sales, in theaters, etc.

A diagramatic layout, embodying the principal features of the phonographic loud-talker as here proposed and as it might be applied specifically for the purposes enumerated below, is shown herewith. Briefly considered, the phonograph attachment would consist of the proper number of cylinder type phonograph records mounted somewhat after the manner shown in the drawing, so that each respective record could be put into operation in response to each push button as becomes evident.

It will probably make the matter clearer to follow thru one stage of operation on such a loud-talker, provided with automatic speaking attachment in the form of a phonograph. Let us consider that this device was to be used on such trains as those operated thru the well-known Hudson River tunnels connecting New York City with New Jersey. The trains running between the Hudson Terminal or Cortlandt Street, New York, make but four stops, and these are shown in the diagram, being respectively Cortlandt Street, Pennsylvania Railroad (Exchange Place), Erie Railroad and Hoboken. Each phonograph record would be made up with the proper number of repetition sentences for each respective stop, as, for instance, the Cortlandt Street record might contain the record, "NEXT STOP CORTLANDT STREET—NEW YORK—ALL OUT," and this might be repeated several times with a brief interval between each sentence.

This idea was conceived for one particular reason, and that is that these trains are gradually being supplied with women guards, and it was noticed by continual every-day traveling on them, and especially when the trains were crowded, that many of the women guards spoke in such a low voice that their announcements of the next station could not be heard beyond a few feet. With this arrangement, which is not only practical, but extremely feasible, the lady guard would simply push the properly labeled button on her key-board, the key-boards to be placed on the frame of the car door at which the guards are stationed, when the following operations would auto-

Why not Make a Real Practical and Useful Application of the Phonograph by Combining it with the "Loud-Talking" Telephone as Illustrated in the Accompanying Views? It Would Save Much Confusion and Misunderstanding in All Public Places, Such as in Subways, Theaters and Stores.
May, 1918

"Vol. 6, No. 1"
By "ELECTRICAL EXPERIMENTER"—Herself

My parents always say that nice people don't talk about themselves and I guess they're right. But today I'm 6 years old, so I know you will excuse me for ont. I know of coarse that littered girls should be seen an not herd, but then I am such a lusty litter thing and so big for my age that I cant help being herd all over the United States an much more ther then that. I am now herd every mons all over the civilized world from New sendall to Norwai, from india to soil, from Transval to Tchina and from Kanada to Djapahn, they all know my voice and wellkom me evry mons.

That's pretty good for a six year old isn it now! ? ? Besides I can't help being loud at Times for my parents put me in each a loud new dres evry mons thet I thinke thei kwer, the Cleveland Plane deeler, the saint-luis Post despatch, a lotsanlots of other nice litter girls all over the country print nise storis about me evry singel mons. and do you know that I am the Biggest electric young girl in the entire world now? Bigger then evry other 3 electric girls combined! I go now to over one-Hundred-
sou-sand peepel every mons! 100,000 good an stancht friends! And no make belif from ether. no sit my friends pai for rise to kom to ther. House, eat, and them, honest. An moni toalks dont it now? Do you woneder that I am prout an a bid stuk up my hands when I haf a bid stuk up my hands when I haf

Of coarse I wasnt allwas so big. Wen I was first borned I wen onli to 3000 peepels Houses evry mons but then my parents got for the Baltimor to the philadelphia to the chigago Tribun, the New York Tribune, the New York sun, the boston transkrit, the philadelphia sun, the chicago Tribune, the New York American, the Siminatti En...
E. L. Blackhouse, desert little Ain't! Can't it? All used? Thei is a knute little sigar liter, o yea!

So dad went an sent all those 100 an hundreds of letters to the Chicagoa Bull-dog sigar liter manufakterer bekaus he thet that maybe thei would give him a big ad for me. Yes like shuger thei did.

An what do you think thei went an rote dad? Thei thent him for all those nine letters but wanted to now if dad was batti in his skilite and what he ment by colling their poor dear good old bulldog a sigar liter when poor thei was a lady kurling iron heater, an not a sigar liter at all!? My wasnt dad soar when he found out the bull hed maid of that bulldog!? the aire arround him was bloo for ours an ours an he triet to blame it on everi one in the plan. Poor old dad how could he hav gesset thei figo is hallo insides of him an thet there is a heating element inside the sides to heat mas or sis kurling iron in ??? But you cant beat dad, for you now what he want an did you never gess. Thei got the nerv to rite those Bulldog pepel that with a littel change thei could convord the kurling iron heater into a sigar liter eng ny an sell em to all those pepel an thet thei should be thankful to him for having gave them sech a good idea all for nothing!?! Can you head it???

But i reeli shouldnt mak fun of dad for he gave me a lot of brant new hats for my 6th birthdal. He calls em headings an he spent a bunch of moni on em and I like em. Doant you think their reel pecchi!?? i do. The one he calls Orakel i think is the nisest an he said over 1000 years ago their

We Were Never so Humiliated in All Our Lives Met so Well and Told You Our February Issue that this most Honorable Dog was found dead in the Street—An. We Thats the Real akan, it Ain't! But what is It? We are Alack it Ain't! It's Too Glaring, so Please Read the Accom-

lived a lady in a desert in a Q-as an her nain was miss Orakel an she told all the people what thei didn't now about an she was awfull wise. An therefor now when my friends wan to know something or other i will tell them all about it thru my oarke there pretty good for a six year old isn't it now!??

Now then i've tol you all the latest gos-sib i want to ask you a favor, a favor for me and one that will help you lotsanlots.

Dad sais that my friends doant read my ads enaf, and thei dont rite often enaf to my advertisry. An he sais that if thei only would and keep it up he could add 32 texd pages to me within 6 mons. Gosh i'd never belief it but the adverstment mangr sais its so, so it must be so after all.

You see dad sent all his moni on my texd dresses and blow in moare on them then he gets bak outo my ad pages, so at the end of the mons he owns hisself moni.

An yesterdai the printr blox in with a new kontrakt an wants 20 percent moare to get me out evry mons. Good nice, i feel dad would ether drop thru the floor into the seller or sale thru the selling but he jest

"Sub"-Detector, Thriller In New War Play

Did you ever hiss the villain? "Ask dad" he knows! In the palmy days of the drama "pop" used to line up in the gallery and watch the villain steal the heroine, only to be foiled by the noble hero who always drops in at the right moment! Then too, we had the wily adventurer who always tried to lure our hero away from his woozy-woozy. Do you remember those days? I'll guarantee not many of you do.

In these more advanced times it's the "movie" villain who holds our attention, and he usually wears a wrist watch! Even then he can't hear you when you try and give him the razzle! Such being the sad and distressing circumstances, energetic producers have awakened to the crying need and presented the American public with a regular old-time drama, imported from England where it has played for more than a year.

Set to American ideas with none of the thrills left out, with a real American hero and heroine, villains, spies, adventuresses, henchmen and all the rest of the "fireworks" handed to you under the title of Seven Days Leave and you have a real, live, heart-throbbing, patriotic war play, that is bound to wake up that slumbering spark and send you looking for the nearest recruiting station.

The story surrounds itself with the expected arrival of Major Fielding at Colonel Sharrow's house, Hampton Sandy, England. He has with him a special device which he has been working on, that will detect the presence of submarines. Incidentally he is in love with Lady Mary Heather, a neighbor of the Sharrows.

He arrives with a model of his wonderful machine and also the working plans of the same. While there, the plans are stolen by German spies who are in the guise of Belgian refugees. Then begins a series of dramatic incidents, thrills, heart-throbs and all thrown in, which lead to the capture and end of the plotters with U.S. Destroyers in action and the final sinking of the submarine—with the lovers united again.

It is interesting to note what novel applications and innovations have been adapted to stage and screen during the past few years.

The accompanying photo is a scene from the play wherein Major Fielding and Colonel Sharrow are testing the practicability of the submarine detector. An electric cable has been laid to the water-front and a sensitive microphone placed in the water. The machine is supposed to show the presence of a submarine and also its position from the microphone. The machine on its test indicates that a submarine is present which causes them great surprise. Later, this proves true and the submarine is blown up.

The cast is noteworthy, and should be commended on the spirit shown through the play. So if by any chance "Seven Days Leave" should play your town or near your town—even if you have to walk twenty miles—by all means don't fail to see it!

—George Holmes.

RUSSIAN INVENTS ELECTRIC MACHINE TO BEHEAD 500 AT ONCE.

Shades of King Henry the VIII, what are we coming to. Modern science has come to the aid of the Bolsheviks. In case they decide to imitate the French revolution and introduce the guillotine, in the person of a Russian engineer named Blum. He has submitted a new type of that instrument to the council of people's commissaries, and which is said to work by electricity; it will behead 500 victims with one stroke! Next!

AVIATORS USE ELECTRICALLY HEATED CLOTHES.

The accompanying photo shows two members of the British Royal Flying Corps donning their electrically heated gloves and foot insoles, preparatory to starting on a cold night trip over the German lines. The current for heating the gloves is obtained from the storage battery or dynamo of the plane. In the aviation service of some of the allied forces electric heating for all the clothing has already been quite extensively adopted. The aviator will thus be enabled to attain higher altitudes without inconvenience from the extreme cold of the upper air currents.
Research and Its Importance to Human Progress

By Dr. Willis R. Whitney
Research Engineer, General Electric Company

Scientific research, or research in the natural sciences and in the industries, might be defined as the pioneer work of the developed country. In this light it is easy to see that our times are new. Not long ago our pioneer work was of another kind. It was opening up the undeveloped land. It was actively and well done. But the work must change, because our requirements have altered.

I do not want you to look at research as an old, established utility. I want you to see it as I do: a powerful factor proved by the advance of the industrial welfare of the foremost countries, and a world-experiment of less than a century's trial, but something still unappreciated in America. It is true that the earliest man and many of the lower animals accomplished ends by research, but I refer now to research in the natural sciences and to the research which in our day is necessary to our desired activities. These sciences are already very highly developed, and advanced education is demanded by them. For example, if I wish to cure physical ills, I cannot expect to do it by reciting ancient incantations, nor by using roots and herbs, as was once customary. I must first familiarize myself with an accumulation of previous experience. I must study anatomy, physiology, chemistry, bacteriology, etc. This is a relatively recent world-condition. Copper, iron and five other metals were known and used at the time of Christ. In the first 1,800 or 1,900 years of our era there were added to the list of metals in technical use (pure or alloyed) about eight more, or a rate below three a century. There has been so much industrial advance made within the past twenty to thirty years that fourteen new metals have been brought into commercial use within this period. This is almost as many in our quarter century as in the total preceding age of the world. Conditions are similar in all the applied sciences. The accumulated knowledge in any field is already very considerable, and to get into the firing line of useful work one must go up past the baggage train of knowledge and experience.

I want you to realize that in America we are going ahead in the future at a rate dependent entirely upon our preparation. Laboratories are a relatively modern thing. In most of the sciences they are a development within the last hundred years. I want you to see that we must be foremost in systematic, organized research or we shall be distanced by other countries which already well recognize the value of new knowledge.

When so much of our material welfare, the condition and extent of our manufactures, the quality of our agricultural efforts, and the health of our people, depend upon the rate of our acquisition of new knowledge, there ought to be much greater effort made along the lines of research than is at present the case. We call knowledge power, but we need to see that new knowledge is the second power of power.

I am in favor of anything which helps train the American student in the path of sanguine research. It can be done by research men themselves, but probably not by others. It is not the knowledge which the student preparing for research needs, so much as the spirit of the investigator. His thoughts should not be fettered by laws, but helped by them to fly. This can be done best by those who are optimistic almost to the extinction of reason.

All service is based on knowledge, and knowledge is an ever augmenting thing which almost anyone may increase. If the stock is eternally useful, as it is, how great must be the value of the indestructible.

(Continued on page 48.)
Modern American Electric Furnaces

By Frank C. Perkins

The accompanying illustration shows the design and construction of a powerful industrial electric furnace developed at Chicago. The photograph shows a 5 ton, 3 phase electric furnace with two electrodes mounted in a tilting roof which may be opened and closed for operation.

In the electric furnace the quality of steel produced is such that it cannot be excelled by any other process, and ordinarily cannot be equaled. The electric furnace is virtually a crucible, with the heat of electric arcs on the inside—thus making it possible to melt and refine steel without the objectionable features of the blast. It leaves the metal freer from oxygen, nitrogen and other gases or slag inclusions.

As to the cost of the produce it is competitive with, or lower than, open hearth, converter, or crucible processes. This is in general due to the fact that steel foundries using electric furnaces make up their entire charge from old scrap, which in any market is enough lower than the combined scrap and pig used for the charge in other processes to offset the quarter of a cent per pound which electricity averages for conversion.

As the material is put directly into the furnace and its constituents are not oxidized unless oxidizing materials are put in for that purpose, the process is simple and the steel maker has the simple problem of having fewer elements to deal with and it is equally advantageous for steel or iron, and will prove as profitable for the small foundry as for the big steel plant. The rapidity of the process as compared with the open hearth practises, saves molding floor space and effects numerous economies.

in the form of labor and other expense. It is maintained that electric steel has greater density and is free from the blowholes that entail so much machining loss when discovered too late, while its tensile strength is 10,000 lbs. per square inch greater than open hearth steel.

Electric steel has an elastic limit from 5 per cent to 15 per cent greater, and its working yield-point is 20 per cent to 50 per cent greater. This is largely due to the freedom of electric steel from oxygen, nitrogen, and slag impurity, while the same heating processes leave in their produce because of the limitations of all fuel-melting processes, and which the electric furnace refines out of electric steel.

The fusing material in the electric furnace is at a higher temperature than the crucible, the heat is applied inside the crucible while in fuel-melting furnaces the heat is applied outside the crucible. Chemical composition of consecutive heats can be held more closely to a standard than with any other process. This is the most noticeable when handling easily oxidizable metals, like vanadium, chromium, silicon and manganese. Alloy additions may be made in the furnace itself rather than in the ladle, which increases the factors of thorium assimilation, diffusion and homogeneity.

When the five ton, three phase furnace has its roof tilted back it is in the charge position. This furnace is equipped with two top electrodes and a bottom connection to the bath. After the charge has been dropped into the furnace, the roof is pulled forward by a motor and sealed with a dry fire clay gasket. The spout is closed and the furnace is practically airtight, resulting in the most rapid deoxidation of the steel. The electrodes are motor operated and an automatic regulator controls the motor operated electrodes.

TO THE U. S. SIGNAL CORPS.

You could get along without the infan-tree, if such a thing should really have to be; you could let up on "typewriting,"

Quit most other styles o' fightin', and keep a battle goin' 'cross the sea; but I'll make an affidavit at my dear old mother's knee there wouldn't be no battles in the trenches 'cross the sea; oh, there wouldn't be no chasnt for them to carry on the war, without the kind assistance o' the U. S. Signal Corps.

Charley Gordon, with a ukelele, sang this at Camp Upton recently... The point may be adduced in vers libre; the signal corps is, after all, the nerve system of modern warfare. Take from the artilleryman the news of what his shells and shrapnel are accomplishing out beyond in the unseen and his big guns are as good as silenced. Take from the infantryman means of quickly receiving and passing along orders—and he's a cooked goose.

ELECTRICITY TO DO ALL CHORES EVENTUALLY.

Thomas A. Edison has said: "The time is not far distant when practically all of the work now done by woman in her home-keeping, so painstakingly and laboriously, will be done better, more simply, without labor, by machine."

A noted scientist recently said: "Whenever you see a man, woman or child doing any form of manual labor, remember, that labor can either be reduced or entirely eliminated by the use of electricity; and that in nearly every case the comfort of the operator can be increased."
Electric "Sherardizing" Prevents Rust

To assure protection against rust a sherardizing process is now standard practice for many electrical and mechanical products where rust prevention is a vital necessity.

Marked improvements in methods of sherardizing have taken place since this practice was first adopted and have resulted in a uniform product with highly efficient protection to the devices so treated.

The process of sherardizing consists of baking the parts to be treated, with zinc dust of the correct chemical analysis, at a predetermined constant temperature, for a period of time depending upon the thickness of the protective coating desired. The zinc is deposited both into and onto the surface to be protected and by entering the pores of the metal becomes a part of the device itself. There is, therefore, no tendency to crack or scale off even when subjected to distortion or changes of temperature.

A feature of sherardizing is that when applied to threaded surfaces these are protected as thoroughly as the other parts and yet can be turned into place with absolute freedom. Neither does it weaken malleable iron castings, since the temperature employed during the treating process is comparatively low.

As a result of the adoption of these methods one of the largest electric companies has developed its own electric ovens for the process and its own testing plant, where pieces of the finished product are subjected to a test of 168 hours in a spray of salt water projected thru an atomizer by a spray jet. This is a condition far more severe than would be encountered in service. Experience proves that the ability to stand this test for a week forecasts indefinite resistance to atmospheric conditions.

The inordinate strength, the durability and the uniformity of the Electrically sherardized coating on steels is not generally understood. To explain these facts a microphotograph is shown in the smaller cut.

A piece of polished steel was electrically sherardized, cleaved to show the connection between coating and steel then magnified and photographed. Note the even thickness of this coating, particularly at the corner. Electric sherardizing made this possible.

The black line between the coating and the steel is the juncture of the two substances. Small as it is shown, this juncture has been magnified 150 times. The final weatherproof coating, if desired, can be given a polish equal to nickel plating.

The sherardizing equipment consists of an electrically heated revolving oven mounted on trunnions which are supported in pillow blocks. The oven is rotated by an electric motor geared to the driving shaft. Metallic resistance elements are placed on each side of the oven and current is applied to them thru collector rings. The best formula for sherardizing can be carried out properly only in an electric oven where temperature, motion and atmospheric conditions can be perfectly regulated.

SCIENCE IN MODERN WARFARE.

The Great War has been called a "grand physical phenomenon" and a "battle of the sciences." To the layman this does not mean very much, but it is nevertheless a fact. It could just as well be called a "chemist's war" or an "engineer's war" or a "surgeon's war," so much has the various sciences contributed toward carrying on the war, says L. L. Edgar, in Edison Life. Most of us do not think of the part science has played in this great struggle. All we see and read of is the terrible fighting and wastage of human lives. It is very interesting to go into the subject deeper and see what has made possible all this fighting, and just where science and its application has to do with modern trench warfare.

Every known science has played an important role, including chemistry, physics, hygiene, mathematics, engineering, geography, geology, metallurgy, geodesy, bacteriology, meteorology, astronomy, and many more of the physical and natural sciences, and secondly, it cannot do without the organization of the different scientific elements in connection with the military establishments.

Today one cannot tell whether the next officer he meets was a soldier before the war or a professor of science in some college. Productive brains receive more care and protection now than any other part of the population.

Let us take some of the more important sciences and see what connection they have in waging war. The astronomer has become an important factor in preparing artillery tables and maps and in perfecting instruments. The statistician is of invaluable help in planning an offensive, as is also the meteorologist. When trenches are dug, the geologist is consulted, as he can tell the best places for shelter, and the probability of striking underground waters. The leader of the war in France, in the person of the minister of war, is a mathematician, and his personal staff are of the same profession.

The science of acoustics, about which, up to the beginning of the war, very little was known, has blossomed out into that of the greatest importance. The French have in use several systems of determining by acoustics the position of enemy batteries. It is possible by these systems to tell to within a few yards the position of a gun fifteen miles away, to determine its caliber, to tell the difference between the discharge, the flight thru the air, and the bursting. The spot from which a shell was fired has been found before the shell landed and exploded. A battery of French thirteen-inch cannon, mounted on a railway truck, fired four shots in an invisible target over fifteen miles.
Electricity Makes the Hens Lay, by Heck!

Can electricity make hens lay more eggs? Yes, say the experts. While in New London, Conn., recently Professor Kirkpatrick and R. E. Jones, of the Connecticut Agri-cultural college, visited the poultry farm of Morton E. Plant, where electricity is being used successfully in increasing egg production. The success of this plan is owing to the fact that the hens eat more feed and a better balanced ration, Mr. Hoover's secretary please copy.

In describing the working of the experiment, Mr. R. E. Jones said there are 6,000 hens on the farm, 1,200 of which are in the experiment. These are divided into groups of 400 birds each. In the first the birds have electric lights and are fed from automatic hoppers, while the lights are on. In the second group do not have lights, but are fed from hoppers, while the third are without lights and fed by hand. The lights are controlled automatically by special electric clocks which it is only necessary to wind twice a week. The automatic hoppers used in the first pen are used only during the lighted hours. At 4:45 a.m. a two-candle-power light is turned on over the roosts, and at 5 o'clock these forty-candle-power lights are lighted in each house. These remain on until daylight and are turned on again at dusk until 9 p.m., when they are replaced by the small lights until 9:15 o'clock.

The greatest increase in production is found in the case of the old hens, it is claimed.

**EDISON-TRAINED BULLETS.**

Two negroes were walking along the avenue discussing the wonderful inventions brought about by the war.

"Yes, sah," one said, "an' a friend of mine who knows all about it says de heah man Edison has done gone and invented a mag-netized bullet dat can't miss a German, kase ef dere's one in a hundred yards de bullet is drawn right smack against his steel helnet. Yes, sah, an' he's done invented another one with a return attachment. When ever dat bullet don't hit nothin' it comes right straight back to de American lines."

"Dat's what I call inventin'," exclaimed the other.

"But, say, how about dem comin' back bullets? What do dey do to keep 'em from hittin' oubl men?"

"Well, mah frier' didn't tell me about it, but ef Mr. Edison made 'em you can bet you'll life he's got 'em trained. You don't spose he'd let 'em kill any Americans, do you? No, sah. He's got 'em fixt so's dey jes' ease back down aroun' de gunner's feet an' say: 'Dey's all dead in dat trench, boss. Send me to a live place where I got a chance to do somethin'.'"

—New York Herald.

**MARCONI COMING OVER.**

It is reported that William Marconi will replace Count Macchi di Cellere, Italian Ambassador at Washington. Count Cellere, it is understood, is returning to Rome and will likely be sent to Petrograd, where Italy is now represented by a charge d'affaires. Senator Marconi, according to these reports, will go to the United States as Italian high commissioner with the rank of Ambassador.

**ELECTRIC "BONES" FOR THE MINSTREL.**

Remember the last minstrel show you saw where the "end men" rattled their "bones" so delightfully? Sure you do! Well the end men of the next minstrel performance you witness may spring a novel surprise on you, for a New York inventor, Mr. Samuel Sussman, has patented a new kind of electric, fire-spitting "bones," which give promise of being a real novelty in the hands of a good minstrel.

The purpose of this invention is to produce a dramatic lighting effect in addition to the rhythmic sounds produced by the performer with the bones and synchronous with the movement of the same.

In the accompanying drawings are illustrated the general arrangement of the invention. Two electric wires connect with two elongated parts made of bone or ebony or some such hard wood. Thru the center of these, are holes drilled part of the way thru for the insertion of wires. At or near to one end of each of the bones and at one side of each, are attached metal spark electrodes. To each of these metal parts is attached one end of a wire.

A suitable portable box is provided in which are resistance coils and a connecting wire, which wire may be used for connection with the electrical supply. There is also provided a bent frame or collar, composed of metal, which may be covered with rubber or other insulator, to be worn under the coat of the performer and at each end of this collar wires are attached connecting the same with the bones. This collar is also connected by wire with the transformer or resistance coils of the metal case.

In operation the bones are placed in the usual manner between the fingers, and, the current of the electricity having been applied, the movement of the operator in shaking the bones connects the metal parts, producing by their contact flashing electric sparks. Needless to say the effect is best produced on a darkened stage.
Fixation of Nitrogen by Electricity

By Theodore Bodde, Research Engineer, General Electric Company

It seems appropriate therefore to explain to the public the reasons for and the meaning of the expression "fixation of nitrogen." First, just what is nitrogen? Nitrogen is a gas present in large quantities in the atmosphere in which we live. In fact, four-fifths of the air which we breathe consists of the gas nitrogen, and only one-fifth part of it is the precious gas oxygen for which our lungs crave, and without which no life would be possible. This nitrogen of the air can also become precious and useful if we make out of it the powerful explosives used not only for breaking up rocks and mountains, but also for fighting the enemy in war time. Then, too, the innumerable plants in our fields and gardens could not live without nitrogen in their food. Our fertilizers are therefore made principally from that element.

The nitrogen is so abundant around us, when in the air it is like a bird in the bush. We cannot catch it, for it is extremely difficult to combine it with other elements into useful material. In fact, it is so recalcitrant to any chemical combination, that only very high temperatures or special chemical conditions are able to overcome its independence and "fix" it to other elements. Once, however, that this nitrogen has been "fixed" or combined with another element, it can be made into a liquid or solid substance, in which shape it can then be handled and transported and done with whatever we please. This is what we call "the fixation of nitrogen."
NEW AUTO HEAD-LIGHT.
In this new auto lamp here illustrated, the manufacturers have designed an exceptionally powerful projector of compact dimensions, that is capable of projecting not only a projected main beam but also a non-glare general diffused illumination.

As we analyze lamp devices, say its inventors, we find that as it appears to the eye there are two sources of glare, one the filament itself and the other the reflector surface. The inventors argue that coloring the light does not enhance the visibility with reduced glare when applied to a unit source. Neither do they believe in the possibility of prismatic deflection nor that a parabola can have an optically correct relation to a multitude of small prismatic lenses with a conglomeration of axial alignments and foci. Therefore the possibilities in glare reduction and still possessing light projection are to minimize the glare due to direct visibility of the light source and to form a main reflector of least aberration and well concealed from the direct visibility.

In this new lamp an attempt has been made to carry out this idea with precision. The light source itself is embraced to the angle of 105 degrees with a spherical curve corrected for aberration and beyond the aperture of the main reflector we have an annulus or spherical curve whose geometrical focus is at an offset as shown in the illustration and therefore the light coming from the filament onto this annulus is not returned on itself but at a distance coinciding with that angle that the frontal screen intercepts. This frontal screen is translucent and light coming from the filament will partly illuminate the same and light coming from the annulus impinges on being slightly beyond the focal point of the main reflector. It also acts as a source of illumination in conjunction with the spherical reflector. The result is a highly efficient projected beam augmented by non-glare diffused illumination.

The inventors have also found that the critical angle reflection for metal reflectors takes place at 52½ degrees. That is whenever a reflector is made to embrace a light source beyond 105 degrees the resultant increase of light flux is a positive detriment to visibility at a distance.

WHEN "UNCLE SAM" TAPS THE WINDOW, YOU LOOK!
This window attraction device is operated by an electric motor and it can be attached to any electric socket, therefore there is no necessity of disturbing your window display when starting or stopping the figure. Its life-like motion of rapping on the window, turning the head and pointing the finger towards the goods displayed, makes it one of the most attractive advertising novelties yet devised.

NEW ELECTRIC SHAVELIGHT FOR SOLDIERS.
It throws a flood of light—not in the eyes, not into the mirror or around the room, but on the face, right where you need it.

The soldier’s days are busy. He must shave, usually at night. And it’s not to be expected that his quarters—often an old barn, farm house, etc.—will be equipt with “all the modern conveniences.” He will, therefore, find this new military style electric light shaving outfit very serviceable.

The outfit consists of a high-grade safety razor, with six crucible steel blades; the electric light attachment that attaches to razor handle; stropper; battery that will supply light for one-hundred shaves; high quality aluminum trench mirror—all complete in a compact khaki case. The light attachment can be used on fountain pen or pencil for writing where light is dim or wanting—also for reading.

An electric apparatus has been devised for giving warning of impending air raids. It is claimed to be especially applicable to factories and public buildings. An electric resonator is placed on the roof, and on the sound of a given pitch being produced, the resonator causes a loud ring in the building until it is stop. It is said that large areas can be simultaneously and instantaneously warned.

A TOY CIRCUIT-BREAKER.
The accompanying illustration shows a toy circuit-breaker for protecting all types of toy transformers against injury from short-circuits. It opens the circuit automatically, and can be closed by push-button only when the cause of trouble is removed. It is low in cost and will be found of interest and service to the junior engineers and electricians who operate miniature electric railroads, motors and other various small electrical devices requiring some form of protective apparatus.

For the Boys in the Trenches or in Camp. There Is This New Electric Shavelight. It Carries Its Own Battery and the Lamp May Be Used Separately When Desired.
The Phenomena of Electrical Conduction in Gases

Part II. How Fast Ions Travel

By ROGERS D. RUSK, M. A.

IONS may sometimes travel at almost infinite speeds. The velocities of these little electrically charged particles depend largely upon existing conditions, but may sometimes be as high as the speed of light itself. This indicates that there is enormous energy back

of these particles, and if we experiment a little we may find this energy doing strange things.

For instance Franck and Hertz, two modern physicists, have recently discovered that when a gas is ionized, light may be produced when the ions become charged. Franck and Hertz worked mostly with mercury vapor, and when they raised the potential between the electrodes, they found the vapor gave off a certain amount of ultra-violet light. When they increased the potential to 12 volts they discovered that just at that point a great deal more light was given off. The first voltage evidently marks the point at which ionization begins and ions receive a single charge. The second voltage evidently is the potential required to give the ions multiple charges, and in each case charging an ion causes the 

emission of light. This is quite in keeping with the electro-magnetic theory of light, and the modern belief in the electric theory of matter, for when the electric charge jumps to the ion the electro-magnetic disturbance in the ether is started. This kind of light may be called cold light, as an increase in the potential from 4.8 volts to 4.9 volts makes little change in the temperature of the vapor, for at the former point no light is given off, while at the latter it is. If some substance other than mercury could be found, giving a greater emission of light, the whole lighting industry might be revolutionized and instead of using incandescent lamps, which waste the most of their energy in the form of heat, we might have lamps operating on 
infinite potentials and giving off little or no heat at all. The nearest approach to such a light today is the Moore vacuum tube light which works however at a very high potential.

The great variety of speeds which an ion may have depends a great deal on the fact that we may have the following four general classes of bodies in an ionized gas.

(1) Single electrons.
(2) Charged molecules.
(3) Neutral or uncharged molecules.
(4) Neutral or charged molecules.

The latter may become charged at any time by ionization thru the agency of heat, X-rays, radium, ultra-violet light, or cold.

fusion with each other. The existence of such ions may be proved by demonstrating the conductivity of the gas, and they may be removed from the gas by straining the gas thru a glass tube fitted with a plug of glass wool, or by bubbling it thru water. It will then be found to be unisoned and nonconducting.

Straining the ions out makes it seem as if the ions must all be larger than the gas molecules which get thru, but this is not necessarily the case as it is most likely their electric charges which make them stick to the glass wool or remain in the water.

It may be well to notice, before going any farther, a very great difference between conduction of electricity in gases and conduction in solids or liquids. The amount of current which may pass thru a conducting liquid or metal varies with the resistance as per Ohm's law, C = E/R. However this is only partially true with respect to gases. The higher the voltage, the more the current falls below the value it should have by Ohm's law until a point is reached that an increase in the potential does not increase the current at all. At this point the current is called the saturation current, because all of the ions are being carried out of the field, as fast as they are formed. Hence this is a maximum value for the current. Its meaning can best be understood from the curve, Fig. I, representing the variation of the current with an increase in potential. The current as will be seen rises rapidly at first, but soon begins to slow down and at last reaches a steady value at A where the slope has become zero. The current then in a gas depends upon the total number of ions being formed in the gas. However, a very interesting phenomenon is noticed if the potential is raised a great deal higher still than its value for saturation. At a certain point the curve will begin to rise again showing that contrary to expectations the current, after having reached a maximum, is now increasing again. The complete curve will now appear as in Fig. 2, where the second increase is found by observation. This is due to the fact that when the potential is raised to a much higher value, the existing ions are swept across the field so fast that they encounter neutral molecules in their flight, and ionize them by collision, thus producing fresh ions, and thereby increasing the number of carriers for the current.

In measuring the velocity of the different kinds of ions the first necessary step is to separate the positives from the negatives. As the first measurements were made on ions in vacuum tubes, this can be easily accomplished by such a tube as shown in Fig. 3. The rays between the cathode C and anode A, are a mixture of both positive and negative ions traveling in opposite directions. However, if each electrode is perforated with a small hole near the center it will be found that some of the positive ions formed at the anode will travel thru the perforation in the cathode into the space beyond it; while the same thing is true of the negative ions formed at the cathode, some of them will have time to open the anode into the space beyond. So far, it has been found that the positives travel with a comparatively slow speed while the negatives may even travel as fast as 186,000 miles per second.

There is a certain class of modern scientists who believe this velocity is the highest possible velocity that anything may ever have. Those who believe this are the upholders of the theory of Relativity. They hold that such realities as time and space cannot exist independently of each other, but are connected by a very close relationship (hence the name Relativity). They say by this relation everything else in the universe is conditioned, and that no velocity can exceed the velocity of light, which is the swiftest form of energy known traveling in the lightest medium, the ether. As this theory has met with a great deal of criticism it is probable that the question will remain open for some time as to whether a higher velocity is possible or not. However, it is interesting to note that the velocities of the ions do approach this value seemingly as a limit. Also this may tend to show that the fastest ions after all are nothing more material than light itself, and we call them unit charges of electricity.

(Continued on page 57)
Capt. E. H. Armstrong "Over There"

All American radio men are acquainted with Edwin H. Armstrong, the young genius who devised and patented the now well-known "Armstrong Circuit" for Audions, by which it became possible to make a single bulb regenerate or develop radio-frequency oscillations, so that undamped, as well as damped, waves could be received and amplified.

We are pleased to reproduce a photograph of Mr. Edwin H. Armstrong, the well-known American wireless expert, who was awarded the medal of the Institute of Radio Engineers for his discoveries in the radio art. Such an award constitutes in itself a recognition of genuine service in the cause of radio science. Mr. Armstrong was born in the United States on December 18, 1880, and after passing, with credit, thru the usual school curriculum graduated at Columbia University, from which he obtained his degree in 1913. Since that date he has concentrated his efforts on the advancement of radio-telegraphic science, working in conjunction with Professor Pi- pin, the President of the Institute of Radio Engineers, in his important research work at the Columbia University laboratories. Mr. Armstrong is himself one of the Directors of the Institute of Radio Engineers, besides occupying the post of President of the Radio Club of America.

Like so many other of his fellow citizens, he has answered the call of his country to aid her in the role she has undertaken in the present struggle, and recently received his appointment as Captain in the U. S. Signal Corps. This young scientist of twenty-eight has already won high distinction by his work in wireless telegraphy. Perhaps the invention most widely connected with his name is that of the "Armstrong Circuits," which have done so much to improve the sensitiveness to reception of wireless apparatus through the instrumentality of the three-electrode valve. Mr. Armstrong has thrown much energy and zeal into the work of the Institute and has made many valuable contributions both to its discussions and its Journal.

Captain Armstrong is now in France with the American Expeditionary Forces. His skill in the radio art will prove of supreme value to the American army.

RADIO SAILORS GET INTO TRIM FOR SEA DUTY.

The accompanying photo is an unusual interior view of the new Austin Hall operating rooms at the Harvard Radio School. Time and especially war will change all things. This room was formerly in more peaceful times, a part of the Law Library study at Harvard. Here the radio operators which are to man Uncle Sam's rapidly-growing battle fleet are taught the science of wireless by experts, many of whom were well-known radio workers in civilian life prior to the declaration of war against the Central Powers. Now one hears the constant buzz-buzz of the radio-telegraphic dots and dashes all day long. The men are not kept at code practice all day long—but as fast as one class finishes its period, another takes its place. Thousands of future naval Radio operators are being taught how to handle wireless apparatus and how to send and receive the mysterious dot and dash messages at this school. Today a battle- ship, or any vessel of the line, would be practically "blind" without its Radio equipment and squad of Radio operators—three to six of whom are supplied to each war vessel.

UNIVERSITY OF ILLINOIS OFFERS WAR COURSES.

A war course in Radiotelegraphy is being offered by the electrical engineering department of the University of Illinois to junior and senior students of this department as an elective. An oath of secrecy and appearance before a notary public by those entering the course, vowing that they will in no way divulge any facts learned in the course to any persons other than Government officials, is required. Apparatus for receiving messages (the receiving sets alone being furnished), with confidential information and instructions for their use has been loaned the University by the United States Signal Corps, Prof. Elery B. Paine, head of the department of electrical engineering, is the instructor in the course.

The department of geology is also offering an interesting course, dealing with the iron and coal factors in the warring nations of Europe, lines of communication and other topics concerning the geography and geology of the war theater. The University has pledged itself to instruct 5,000 soldiers, either engineers or regular soldiers, for skilled war service in the departments of mechanical and electrical engineering, including laboratory and shop practice. Announcement has also been made that the ground school of the work in military aeronautics will be doubled in size, providing accommodations for 1,200 students.

Speaking about the capacity of condensers, are you aware of the fact that the entire capacity of the earth is only .707 microfarads?
RADIO TAUGHT IN NEW YORK TRADE SCHOOL

There is a great demand for radio men in the Signal Corps and to meet this need classes have been formed in many parts of the country. One of the most interesting in New York City is that held at the Stuyvesant Evening Trade School. Only men who will be called in the second draft and who have been examined and placed in Class 1-A are eligible.

As these men are still earning their bread and butter, they can only do this work in the evening. Despite of this fact the results are extremely good. The men are heartily and eager to gain the required proficiency of sending and receiving 20 words per minute. This is the standard speed set by the Signal Corps. Thus the patriotic devotion of the instructors it has been found possible to have these evening classes free.

The equipment used in teaching the radio classes is of the best and very latest type. The head-bands are of the new single bar type widely used in the government sets and weigh less than any other style so far designed. The tone buzzer used is a new design giving the true 500 cycle spark pitch, so that the students are trained under as near working conditions as possible. This is more important than it might seem at first, for if the student is accustomed to hearing the signals on a low pitch tone he is very liable to be confused when he first hears a "real" wireless signal coming in on a high pitch note.

In an interview with Mr. T. H. Know, principal of the school, as well as Jacob Weiss, Head Instructor, we were informed that the instruction is entirely free, all apparatus being furnished. All the drafted Class 1-A men are eligible, and all those that are subject to call. The school can still accommodate a few more men.

We see no reason why wireless amateurs should feel discouraged on account of the closing of their radio stations. To us, we see an opportunity for the amateur to fix up his set to perfection, study up his theory, and when the war ends be ready to do efficient work.

Wireless communication was first established between Japan and the United States, July 27, 1915.

ELECTRICAL EXPERIMENTER

NEWS OF BUENOS AIRES—NEW YORK RADIO

By Leon Gireaud.

I am pleased to inform the readers of the ELECTRICAL EXPERIMENTER of the progress of wireless telegraphy in this country.

In the first place, we have the arrival of the American engineer, Mr. Charles Edbridge, who comes to direct the work of installing an ultra-powerful radio-telegraph station for direct communication between Buenos Aires and North America, the concession having been granted to a North American company a year ago. This plant will be installed in San Isidro (near Buenos Aires), and the plans have already been approved by the government. Recently, however, some modifications have been suggested. The original plan called for the antenna to be sustained by three towers 300 meters high (about 1,000 feet), but in the modification two have been suppressed. The transmission system will be such as is used in nearly all of the large stations—Poulussen 500 kw., length of wave 24,000 meters. Altogether there is no station in the city, it will have direct communication with the offices which will be established in the central boro. The price of this station is calculated to be $750,000 (American currency).

It is also worth mentioning the attempts that have been made to communicate with Nauen (45 km., from Berlin). The interested parties secured a three months' authorization to erect a station which they placed on the Florida farm in the Pleiner station. The characteristics of this station were as follows: the most modern type of receiving apparatus was used, including a Lieben valve; the copper wire antenna was sustained by 16 posts, 32 meters (105 feet) in height, and a wave length 8,400 meters; the ground constituted a network of iron wires, 800 meters (about 2,600 ft.), long, interred in the form of a fan at a depth of 1 meter; the antenna has the same reach toward the east as that of Nauen; taking into account the distance between Nauen and Buenos Aires, which is in a direct line, 13,000 kilometers, there are various difficulties.

Notwithstanding these difficulties, the constructors have been able to get into direct contact with Nauen, but owing to the great atmospheric discharges (static), have not been able to decipher the messages; these discharges are due partly to the form of the antenna, which, because of their length and height, cut thru various atmospheric strata, producing violent discharges which disturb the reception.

Nauen has a power in the antennae of 200 kw. and a wave length of 8,000 meters. Before rupture with the United States, it was supposed to be 300 kw.

At the end of the three months, the constructors asked the government for an extension of time of one month, stating that they had not been able to communicate owing to the fact that they did not know the exact time when Nauen transmitted with entire power. We note that this is not true. After several days delay, the Secretary of the Navy appointed an engineer to investigate and determine as to the probability of their having received messages from Nauen. The report was unfavorable, and he ordered the dismantling of the station.

It is probable that they were able to receive perfectly, since in 1913 the "Cape Trafalgar" could communicate with Nauen from S. de Bahia, Brazil. At that time the

WOMAN OPERATOR IN THE U. S. COAST GUARD.

Yes, the women are bound to get to the front in this war. Here we have Mrs. Myrtle Hazard, Hailing from Baltimore, Md., a Hale and Hearty Radio and Morse Operator. Now in Uncle Sam's Coast Guard Service.

Mrs. Myrtle Hazard, who is from Baltimore and the only woman electrician in the United States Coast Guard. She is one of the few women radio operators in the government service. She learned the job in four months' study at a class in the Baltimore Y. M. C. A. and past the difficult government examination easily. She is both a Radio and a Morse operator.—Photo Harris and Evans.
External Grid Vacuum Valve Construction

A Unique and Simple Means of Making Experimental Amplifiers

By R. U. CLARK, 3rd

SINCE the introduction of the first real practical hot filament detector into the radio field, it has been the one great ambition of every wireless amateur to construct experimental vacuum valve detectors for personal use. Sad to relate but very few workers in the past have had the means necessary to perform much research work in this branch of the art, owing chiefly to the expensive apparatus required for the actual construction of the bulbs.

It is regrettable that the above should be the case—especially in view of the fact that the particular instrument under consideration may still be considered in the embryonic state, and quite capable of being vastly improved.

The present high cost of all good detectors of the valve-amplifier type precludes the possibility of their being used, in furtherance of new ideas, except by those with money to spare, and in most cases places them beyond the reach of many earnest workers.

After a considerable expenditure of time and money, the writer has evolved a very simple and inexpensive method of making experimental vacuum valve detectors, of the external grid type, which will be explained at length in this article. It is the hope of the author that the idea involved, which has been thoroly proven, will be of great interest to a large class of readers. Certainly no one field offers more opportunities of interest to experimenters than the one in mind.

Considerable incentive and encouragement may perhaps be found by others in the fact that, after the direct output of much little work, the actual discovery of the double filament bulb, that plays the all-important part in making our experimental detectors, was the result of chance. During a few minutes' respite, spent in looking through a motor magazine, the writer became aware that the solution of the problem of making valves was staring him in the face in the guise of an auto head-light bulb with two filaments.

It often happens that such discoveries are the result of chance, but the fact remains that unless the particular finding fits in with the line of work being undertaken at the time of enlightenment, the incident will be forgotten or prove of little use. The author, and probably many others—had often thought of using the "High-low" type of electric light bulb for constructing valve detectors, but had always given the idea up as impractical. It remained for the urge of real necessity to demand that every possible means be given a thorough trial.

As may have been already surmised, the real workable valves which are illustrated in the views accompanying this exposition, are not only of the external grid type, but also have two filaments, and thus double life to the instrument. It will be at once apparent that, since the bulbs contain two separate filaments and circuits within them, that one is to be heated by the low voltage battery, and the other is intended to constitute the plate, and when used as such its two wire leads will be short-circuited. When one filament has burned out in use it will be reconnected to form the plate, while the other filament, formerly acting as a plate, will furnish the heat necessary to throw out the stream of desirable electrons, on which the whole action of the device depends.

In the first illustration there is shown a view of the "High-low" auto head-light bulb which does the trick. This lamp should be purchased in accordance with the following specifications, and if not obtainable at any of the big wire supply houses in the reader's home town, they can be had from the makers or others as listed elsewhere in this issue. The bulb which the author, after a good deal of searching, has found best suited to the peculiar requirements of the valve detector is rated as follows:

Maker's Number Volts C.P.
T. 14 6-9 4 & 12, also 12 & 18 C.P. semi-

Macro's with double-contact bayonet base. Usual retail price 80c, with 35% off on lots of 5, making the price 55c each.

Unless these lamps are specially ordered, send stamped self-address envelope to the editor and names of concerns supplying these lamps will be sent gratis.

From the makers, and specified in this case "without bases," it will be necessary to carefully remove the brass ferrules and separate compound, which holds together the lamp base, after first cutting the connecting wires away at the contacts to which they are soldered. This work is best done with file and a pair of nail-pincers, and much caution should be observed to prevent accidental breakage.

It will be taken for granted that the experimenter intends to prepare more than one bulb for the initial try-out. Altho there may be a slight difference noticeable in the behavior of different bulbs of the same make, the variation will be found in most cases to be very slight. The first bulb tried out, however, might be defective; hence the advisability of using more than one lamp in testing out the idea involved.

A word at this point in regard to the operation of the valves under consideration may save much trouble later, on in the game. A good deal has been said against the hot filament detector which is manifestly undeserved. It has been repeatedly stated that, unless exhausted of air to a very exact degree, devices of this nature will prove worthless as detectors. Quite naturally, this is true to a certain extent, but it is often possible to obtain almost equally good results from valves which may vary in this particular, provided the operator is willing to work to find the optimum point of filament luminescence and high voltage adjustment, as required for the utmost sensitiveness under varying conditions of vacuum within the bulb at hand.

Another point worth mentioning is that of the strange and oftentimes erratic action of this class of detectors after they have been considerable use, which calls for the same solution as above stated. The fact is that probably no one thoroly understands these bulbs as yet.

Before fitting up the lamps as detectors, the wires which lead to the inside should be tested for a possible short-circuit which must, of course, be avoided, except as explained elsewhere. In order to gain a clear conception of the new bulb circuits, which are to be obtained by rearranging the filament leads, the reader is asked to refer to the diagrams in Fig. 2. In this drawing the view A represents the normal connections as made by the manufacturers. At the point I in this view the wires should be disconnected. At B and C, same figure, the correct wiring plan for using the upper and lower filaments respectively, at incan-
descence, is shown.

MINERALS FROM BROADWAY, NEW YORK.
"What you can't get in New York, you cannot get the world over," is one of the proverbs of New York. While many curious things are found along Broadway, it will probably come as a surprise to many, that Broadway is one of the most curious mineral centers in the world. Very few people realize that on Manhattan Island over 118 varieties of minerals have been found—not only minerals, but real gems.

For instance, on Broadway and 157th Street, there have been found aquamarines weighing 1 1/2 carats. From this locality also come brown tourmaline, golden beryl and rock crystal, which can be cut into gemstones. Of particular interest to the electrical man is the fact that on Broadway and 176th Street there are found, besides beautiful green tourmaline gems, magnetite and iron ore, chalcopyrite, malachite and pyrrhotite, also a source of nickel in a crystal form, which is considered quite rare in any locality.

Many other rare minerals in addition to the few listed are used in the manufacture of the perikon detector; also the lead mineral roselignite. Other minerals of interest found along Broadway are agate, amazon-stone, amber, amethyst, crysoberyl, fire opal, garnet, peristerite, prehnite, rock crystal, rose quartz, smoky quartz, precious serpentine, tourmaline and willenite.

The commercial minerals include silver, lead, zinc, copper, iron, feldspar, molybdenite—which is used in the molybdenite detector—garnet, amethyst, mica and beryl. The radio-active minerals attinite, torbernite and uraninite are also noted. Also a very good grade of iron pyrite called the "common fool's gold" has been found in fair quantities in the upper parts of Broadway. Iron pyrite, as is well known, is an excellent mineral for detecting radio signals.

FREAK OF RADIO.
A peculiar phenomena which has never been explained well is that which takes place at several points along the Atlantic Coast. There are times when a vessel in radio communication with another and the signals gradually die out and then increase to their normal sound. A similar effect has been noted by amateurs also, when sending in one direction can cover much greater distances.

Zeppelins can attain a height of 18,000 feet, or about 3 1/2 miles. They easily remain in radio communication with their home stations.

MICROPHONE "HOWLER" FOR CODE PRACTICE.
Here is a photo and wiring diagram of three handy pieces of "Bug" laboratory apparatus showing what can be done with odds and ends of a wireless experimenter's assortment of instruments which are now idle. It consists of a telegraph key made on the principle of a Vibroplex, and it works, too, having tried it out on long telegraph lines of the A. T. & T. and Central Union Telegraph Co. A handy box for it is made from light hardwood, so that connection may be made from each pair of cells, spring clips can be seen at the end of the box, for each pair of battery-ends have these spring clip connectors.

This Genius Has Built His Own "Hy-Tone" Microphone Howler for Practising the Code. By Varying the Distance Between the Microphone and Receiver, Tone Can be Changed at Will.

The box now has a capacity for 24 cells but only 12 have been placed in it. This gives me a range of voltage from 3 to 10 at the present time.

Best of all is the contents of the small box, a tele-phones transmitter, telephone receiver placed rigidly in an extension telephone bell box, and made into a "howler" in imitation of the Sayville, L., L., station wireless tone. It gives a remarkably clear shrill tone of a frequency of 500 to 800 cycles, depending on the distance the receiver is mounted from the "howler" box. The transmitter being solidly mounted in grooves cut in the edge of the box and the receiver mounted on a screw, similar to the method used in adjusting the magnets of a telegraph relay.

Several "wireless bugs" have listened to the tone of this "howler" and pronounced it an excellent reproduction of the Sayville tone. A home-made induction coil made on one bobbin of a buzzer, and wound with a resistance ratio of 1 ohm to 50 ohms, is connected in series with the battery and transmitter-receiver and the receiver connections are taken from the secondary winding of the coil as shown in diagram. When telephone receivers are being used, the box is packed with cotton and a lid put on it so the sound of the "howler" will only be heard in the 'phones.

The ratio of the resistance of the windings of the induction coil is not according to Hoyte. I found that I only had that much wire to put on it, but a pair of receivers on the secondary winding gives the proper amount of tone to the receivers to make it sound as if its name-sake were really coming in. The "bug" key can be made from odds and ends which most every amateur has in his work shop and it surely beats sending with the old style key.

NO. 8—DETECTORS.
From time to time we will describe one particular instrument used in either the radio transmitting or receiving set, explaining just how it works, and why. We have received so many requests from new readers asking for such explanations that we have decided to publish this matter in serial form. In the course of several issues all of the principal transmitting and receiving apparatus will have been covered. The subject for the eighth paper is DETECTORS.

![Diagram](image)

The Principal Types of Radio Detectors Are Here Illustrated and Described. The Detector Is One of the Most Important Apparatus Used in Receiving and Translating Wireless Messages and Should Be Very Carefully Studied.

In all modern radio receptors, especially in those sets used by the army and navy, the detector is one of the most important parts of the whole equipment. It has been developed and refined until at the present time it is quite a respectable instrument, as far as its efficiency is concerned. The detectors now in use classify broadly into three groups, viz.: mineral rectifiers (without battery); mineral rectifiers (with battery), and vacuum valves. Each class of wave interrupter and translator seems to fulfill certain requirements best. Where the vacuum valve would prove too sensitive and delicate, as in mule pack sets, etc., the mineral type detector proves best. Where the radio set is subject to fair treatment the vacuum valve or Audion detector proves feasible. For trench and field work the mineral detector is pre-eminently the type to use; it is once rugged, simple in operation, always reliable, easily repaired, and last but not least, it requires no battery. An Audion detector is, on the other hand, liable to breakage, disarrangement of the electrical system, requires frequent adjustment, and must always have a fresh battery to light the filament, besides a 40 to 60 volt dry-cell battery for the wing circuit.

The minerals most in use as rectifiers of rendering them capable of operating the telephones at an audible frequency. This rectification process is shown graphically in Fig. 1 at A, B and C. Curve A shows several damped wave trains as rectified on a radio antenna; curve B delineates these wave trains rectified by the detector so that the current is allowed to pass only in one direction, while the dotted line indicates the form of current pulse passing thru the telephones, where the rectified current is smoothed out by the inductance of the telephone receiver windings. Thus it is seen that what the operator hears in his head phones is not the high frequency aerial oscillations, but a rectified pulsed current having a (group) frequency corresponding to the frequency of the current charging the condensers at the transmitting station. If it employs a 300 cycle detector, the operator at the receiving station hears a 300-cycle note in his head phones, etc.

As to the hook-ups used with the mineral detector, let us glance at Fig. 1. This shows how a non-battery mineral, such as galena, iron pyrites or silicon, is connected up in a simple tuned circuit comprising aerial, tuning coil C, and ground. A high resistance pair of phones is invariably used in such systems, connected either across the detector or the fixed condenser as the dotted line indicates. Fig. 2 illustrates how the battery-using mineral is commonly hooked up with a potentiometer having several thousand ohms. A heavy duty circuit and now used in the Signal Corps outfits is shown at Fig. 3-A. Here the current passes around thru the secondary of the loop transformer. Three volt or 2.5 volt cells is usually the potential applied across the terminals of the potentiometer. The potentiometer slider (or switch) is adjusted until the maximum strength of signal is heard in the 'phones. Also the direction of the current thru the mineral is important and it is well to provide some means of reversing the switch in the battery circuit so that the current can be reversed thru the detector. The mineral is usually connected to the negative battery line.

The Perikon Detector was developed by Dr. G. W. Pickard. This detector consists of two crystals—copper pyrites (Cu Fe S) and zince (zinc oxide ZnO), between which contact against each other in the manner shown. The copper pyrite crystal is mounted in a cup mounted on a spring-actuated rod provided with a suitable knob, by which it can be swung in any direction. Zince crystals are mounted in a large cup containing several pockets, the mounting of both of the minerals being effected with a low fusing solder, Wood's metal or Hugonoi alloy. The action of the Perikon detector is supposed to be based on the rectifying principle previously described; that is, it will pass current in one direction but not in the other. The receiving radio frequency oscillating (alternating) currents in the aerial are rectified and caused to give a sound in the high resistance phones connected to this detector. This detector is invariably used with a battery of about two cells and the potential applied regulated by a potentiometer. When using a battery the polarity of the current must be such that the positive wire is connected to the copper pyrite crystal.

Design for a Panel Transmitting Set

By James R. Hopkins

Did you ever consider that compactness and efficiency in wireless means success? Many amateur wireless operators place their transmitting apparatus a good distance apart so that each instrument may show off to its best advantage, and by doing so they little consider the unnecessary length of the connecting leads, which offer great resistance and very often lack of resilience in the circuit, thus producing unsatisfactory results.

For the benefit of those who are looking for success I shall endeavor to describe a Rotary Gap, panel type, transmitting set, which is not only very efficient but offers a good appearance. A set of this type makes possible very short connecting leads, which are absolutely necessary in an efficient short wave radio transmitter.

The arrangement of the apparatus should be clearly seen by the accompanying drawings. Compartment A contains the transformer embedded in sealing compound. B is the adjustable condenser, consisting of twelve 8x10 inch glass plates, coated with tinfoil 6×8 inches; these are connected in sections of two plates each and controlled by switches C, mounted on the panel. Compartment D contains a rotary gap of the ring type; the ring and rotary arm should be made of Bakelite. E is a protective device to carry off kick-backs and may be of the carbon rod or of the condenser type, as the builder prefers.

The oscillation transformer F is of the pancake type. A resistance coil G is placed in series with the rotary gap motor to vary its speed, and the light H may be connected in series with the transformer for short distance work.

I am not able to give any fixed dimensions, as transformers, motors, etc., vary considerably in size; with the 1/2 K.W. set I am using, the cabinet is 12 inches long, 6 inches wide, and 18 inches high, built of 1/2 inch birch, with the exception of the panel, which is of black fiber 1/4 inch thick, this being firmly screwed to the case to prevent warping.

The hook-up is given in Fig. 1 and the general scheme of arrangement is shown in the side and back views in Fig. 2, while the front view (photo) shows the panel on which all control switches are neatly mounted.

If the general idea of construction is carried out, I am sure the builder will be greatly pleased with the results. I used this set with great success for over a year prior to the war.

A UNIVERSAL SOLDER.

A very novel scheme for making a solder that beats the ordinary solder is as follows: Mix with a good brand of soldering paste as much granulated bar or wire solder that possibly can be mixed (which is done for the sake of economy) and a solder of excellent qualities will be made. It is useful to the electrician in the wires "pin on the celling" can be soldered by applying this mixture, and it is then only necessary to apply the heat of a match. Many other ways for its use will suggest themselves to the everyday practical man. In fact, it will save lots of soldering from being wasted by dropping to the floor. This is the case when applied by the old method.

Contribution by E. DUSKIS.

TO STOP LIGHTS FlickERING.

Many radio amateurs who are annoyed, and are annoying others, by drawing too much current from their supply lines, might be interested in a way to remedy this. The diagram illustrates this without much description; a few words will not be amiss however.

Balancing Radio or High Frequency Transformers With Lamp to Prevent Flickering of Lights on Regular Lighting Circuits.

This idea is not recommended for powers exceeding one half kilowatt as the cost of operation is higher. The writer uses this with entire satisfaction on a transformer of 300 watts input; to balance this current consumption, a lamp bank consisting of three 120 watt carbon lamps is used. In the case where a transformer of higher or lower rating is used, the lamp-bank or any other resistance must be made exactly according. If important to use nothing but silver contacts on back end of key lever, of the same size as those used on transformer circuit; it is well also to have as little vertical play as possible.

Contribution by L. H. REINER.

DETECTING PHONES WOUND WITH GERMAN SILVER WIRE.

The use of high resistance 'phones for use in wireless telegraphy has led many unscrupulous manufacturers to wind their 'phones with German-silver wire, getting the necessary resistance without the efficiency of the copper wire wound 'phones.

This cannot be detected by measuring the resistance and since in many cases a few layers of copper wire are wound on over the German-silver, it is rather difficult to detect these inferior instruments.

However, we can take advantage of the fact that the coefficient of resistance of copper is much greater than that of German-silver. It is only necessary to connect a galvanometer in series with the 'phones and a few cells of dry battery. On closing the circuit note carefully the reading; allow the current to flow for several minutes and if the galvanometer needle gradually drops back you may be sure the windings are of copper wire; but if the needle stays at the same point or nearly so for several minutes, the windings are of German-silver.

Contribution by T. W. BENJAMIN.

A CORD TIP TERMINAL.

It's Always a Mean Job to Properly Connect Cord Tips to Apparatus. Here's a Good Way of Bending It.

Take a piece of springy metal, one inch long and 1/4 of an inch wide. Put a small nail in the middle and bend the strip of metal as shown, and bore a hole in each end to fit a screw. It will be the saving of much time and patience.

Contribution by L. SIMMONDS.
Theory of Tuning, Wave Lengths and Harmonics

By Prof. F. E. Austin

Instructor of Electrical Engineering, Thayer School of Civil Engineering, Dartmouth College

SO-CALLED resonance is of very great importance in the operation of wireless apparatus, and every operator should have a good working knowledge of the theory of resonance and of its practical application. Even the experimenter will work to much greater advantage, with a knowledge of the fundamental law and its careful application, in making and operating tuning coils and similar devices.

When a coil, consisting of a number of turns of insulated wire, is connected in series with a condenser, and an alternating pressure applied to the terminals of the arrangement, as indicated diagrammatically in figure 1, the alternating current in the arrangement indicated by an ammeter connected as shown may be express by:

$$I = \frac{E}{\sqrt{R^2 + \left(\frac{2\pi f L}{2\pi f C} - 1\right)^2}}$$

If a direct current pressure, having the same numerical value as the alternating pressure be applied to the same arrangement, the ammeter will show no indication at all; the condenser, having a very high resistance, really prevents any direct current from passing. Of course, a direct current does exist while the condenser is being charged, but this is so small the ordinary ammeter will seldom indicate this minute momentary current. With an applied alternating pressure, however, the result is very different: since the condenser is very rapidly charged and discharged, the ammeter indicates the presence of the current continuously.

Considering now the different symbols employed in the given equation it may be noted first that the numerator \( E \) denotes the applied alternating-pressure, having a frequency denoted by \( f \) (\( f \) means the number of complete cycles per second). \( R \) denotes the resistance of the coil, expressed in ohms. \( C \) the capacity of the condenser in farads, while \( L \) denotes the so-called coefficient of inductance of the coil, express in henrys. \( L \) depends upon the square of the number of turns of wire of which the coil is composed; that is, of two coils of the same general shape, the one having twice as many turns as the other will have four times the inductance.

Also a coil having an iron core will have very much greater inductance than the same or a similar coil without the core. When, as in wireless work, it is desired to employ very high frequencies, coils having no iron cores are used, since they may be magnetized and demagnetized very quickly and without absorbing an excessive amount of energy. The symbol \( \pi \) denotes the value of 3.1416.

It is instructive to note that if the condenser be removed from the circuit and a direct-pressure be applied to the terminals of the coil, the direct current may be express by \( I = \frac{E}{R} \); that is, according to Ohm's law.

Now, by looking at the first equation it is evident that the last equation may be obtained from the first when the numerical value of \( 2\pi f L \) is made equal to \( \frac{1}{2\pi f C} \).

When such numerical relationship obtains in any case, then resonance is said to exist.

The value of \( \pi \) is, of course, a constant at all times and the value of \( f \) is definitely fixed for any given circuit. It is, therefore, apparent that with a given fixed value for \( 2\pi f L \), a similar numerical value for \( 2\pi f C \) may be found by varying the value of \( C \).

The value of \( C \) for any condenser depends upon the number of sheets of dielectric used in making the condenser, upon the kind of material the dielectric consists of, upon the size of the dielectric sheets, and upon a numerical constant which is dependent upon the kind of units employed in expressing size or area, and thickness.

The capacity of ordinary condensers made up of sheets of dielectric and metal plates, may be express by:

$$C = \frac{\pi n a n}{t}$$

In the equation \( A \) denotes the area of each dielectric sheet in square inches, \( n \) the number of sheets used, \( k \) the so-called coefficient of inductive capacity, and \( t \) the thickness of each dielectric sheet in thousandths of an inch; that is, in mils.

The coefficient of inductance of a coil having an iron core may be approximately express by:

$$L = \frac{4\pi n^2 A}{b \times 10^6}$$

Henry's.
ELECTRICAL EXPERIMENTER

May, 1918

in which \( \pi \) has its usual value, \( \omega \) denotes the number of turns of wire wound on the coil. \( A \) denotes the area of the hole thru the center of the coil, expressed in square centimeters, and \( b \) denotes the length of the coil (not of the wire), expressed in centimeters.

Returning to the consideration of the initial equation, and restating the condition for resonance as when \( 2\pi f L = \frac{1}{2\pi f C} \) it is evident that the equation may be changed to:

\[
2\pi f C = \frac{1}{2\pi f L}.
\]

The reason for the latter arrangement of the equation is because it is much easier to construct a coil to produce a variable inductance than it is to construct a condenser to give a variable capacity.

Considering the last equation, it is evident that if \( 2\pi f C \) has any given numerical value, with a definite value of frequency (value of \( f \)) then some value may be given \( L \), so that the numerical value of \( 1 \) shall be equal to the numerical value of \( 2\pi f L \) of \( 2\pi f C \).

Also decreases.

To make the matter clearer and more concrete, it will be well to assign definite and practical numerical values to the various symbols in the last equation. Let us suppose the frequency \( f \) of the applied alternating pressure is 60 cycles per second; then \( 2\pi f \) is equal to very nearly 377. Suppose further that the capacity \( C \) of the fixed condenser is 10 microfarads or

\[
0.00001 \text{ farad}.
\]

One million microfarads are equal to one farad. According to this assumption \( 2\pi f C \) becomes equal to 377 \( \times \frac{1}{100,000} \)

Next suppose that \( 1 \) \( \text{farad} \) equals .00377.

Then, since \( 2\pi f = 377, \frac{1}{2\pi f C} = \frac{1}{100,000} = .00377 \).

If, therefore, a condenser having a capacity of \( \frac{1}{100,000} \) farad is connected in series with a coil having an inductance of 0.073 henry, then resonance obtains in the circuit for a frequency of 60 cycles, and the current in the circuit is a maximum. The numerical value of the maximum current is

\[
\text{given a maximum,}
\]

depends upon the numerical value in volts of the applied pressure, and upon the resistance in ohms of the coil or part of the coil that is connected in the circuit.

Suppose the pressure is 110 volts and the ohmic resistance of the wire on the coil is 10 ohms, then under the conditions of resonance mentioned, the current will be

\[
110 \div 10 = 11 \text{ amperes}.
\]

A very striking and important phenomenon should be noted at this point, namely, the numerical value of the drop in pressure between the terminals of the coil and also between the terminals of the condenser. The drop in pressure between the terminals of a condenser when resonance obtains in a circuit is express by

\[
\frac{1}{2\pi f} \times 100,000 = 2915 \text{ volts (approximately)}.
\]

The pressure drop between the terminals of the coil may be stated by:

\[
\sqrt{R^2 + (2\pi f L)^2} \text{ which is numerically equal to } 11 \times 10^4 + (377)^2 = 2915 \text{ volts very nearly.}
\]

This condition of affairs seems a bit uncanny. It does not look exactly logical that the pressure between the

(Continued on page 59)
Building an Electric Piano Player

By CHARLES HORTON, Consulting Engineer

Contrary to the general opinion among amateur mechanics the automatic piano, aside from the instrument proper, is a comparatively simple thing. There have been developed commercially two general types of player actions, the electric and the pneumatic. The operation of the latter is as follows:—There is provided a pair of bellows arranged to be worked by the tread of the player which supply the air to run the motor for moving the record and for striking the notes. These bellows do not, as would naturally be supposed, compress air to operate the mechanism but merely it; in other words, the device operates by suction. The use of suction instead of compression is had because of the advantage that since with suction the air is drawn in thru the holes in the record, there is a strong pressure on the record causing it to adhere closely to the tracker bar and thus preventing the striking of accidental notes. Thus it is seen that the foot bellows draws air from the reservoir provided, and this suction causes the driving mechanism to turn the record feeding roll. Whenever a hole in the record comes over the tracker bar, air is permitted to pass in thru the corresponding tube and this air relieves the suction in one of the key-striking bellows, allowing it to spring open and strike the proper note.

So much for the pneumatic type of action. The electrical mechanism is similar to the action of the pneumatic except that contacts take the place of the holes in the tracker bar and magnets take the place of the bellows while a motor drive is provided to turn the record roll.

At first glance the construction of an electric action would appear to be somewhat beyond the ability of the Amateur, but a detailed examination of the apparatus herein described will show that there is nothing at all difficult in the work: but owing to the large number of similar parts the work requires a good supply of patience and persistence. However, the result is well worth the effort, particularly when it is understood that the costs of a commercial attachment runs into the hundreds of dollars.

The arrangement here described is similar to the commercial electric mechanism but is very much simplified. The record is driven by a small hand-crank (or may be driven by a small electric motor) by means of which, also, the tempo is controlled while the ordinary pedals of the piano are used in the regular manner. The loudness may, if desired, be controlled by a simple rheostat and when one has had some practise in the manipulation of the apparatus, one can get very nearly perfect expression from this simple instrument.

The apparatus takes the form of an oblong cabinet which is adjusted just above the keys of the piano and is held in position by its own weight. The record reading mechanism (translator) is mounted on top of the same as is clearly shown in Fig. 1. There is provided one magnet for each key of the piano and one corresponding contact on the tracker bar.

The apparatus plays the standard paper music rolls which range in price from ten cents to several dollars and permits the reproduction of all the standard music at a very low cost.

The construction of the simplified apparatus will now be explained in detail. Referring to Fig. 2 in connection with the following description the arrangement of
parts may be made clear. This view is a transverse section of the box containing the striking magnets. \( A \) represents one of the white piano keys, \( B \) one of the black keys and \( C \) the supporting board for the magnets. All the striking magnets are mounted on this board which is screwed to the two side strips \( 4 \), in order to prevent it bending under the weight. A detachable top \( 5 \) is screwed to these two side pieces, which arrangement allows easy inspection of the striking mechanism. Reference to Fig. 3, in connection with Fig. 2, will serve to make clear the arrangement of the magnets, etc. This illustration is a view looking down on the top of the striker box, and delineates part of the top board broken out to show the arrangement of the magnets. There are, of course, seven white keys and five black ones to each octave of the piano; consequently twelve magnets have to be provided for each octave. One magnet is mounted above the center of each key and in order to find room for so many magnets they have to be arranged in the manner shown, i.e., in four rows.

Each magnet consists as shown of a brass or aluminum tube, detail \( 6 \) (this tube must not be iron) on each end of which is forced an iron washer \( 7 \). Brass is best for the tube \( 6 \), so that the iron washers may be soldered on. The end near the lower washer \( 7 \) extends downward, thus forming a projection which enters a hole in the supporting board \( C \). The bobbin formed by the tube and the two washers is wound full of number 18 double cotton covered magnet wire, thus forming a solenoid for actuating the keys. The magnets are secured to the supporting board \( 3 \) by means of several \( 1/4 \) iron stove bolts \( 9 \), which also, together with the iron washers, complete the magnetic circuits. Within the tube \( 6 \) is arranged to slide freely the iron core \( 10 \), screwed into the bottom end of this iron core is a long brass screw with a round head which is covered with chamois to form a hammer as illustrated in Fig. 2. When the circuit containing any one of the magnets is completed, current flows around the bobbin \( 6-7 \), and causes the iron core \( 10 \) to quickly move downward, thus striking the corresponding piano key. As will be seen by examination of the detail drawings, the entire bank of magnets is divided into seven groups, each group consisting of seven white-key strikers and five black-key strikers. This arrangement is advisable in order to make the assembling easy and also permits the correct placing of the strikers above the keys without extremely accurate layout work.

In Fig. 4 is shown a front view of the record carrying mechanism, usually called the translator. This is to be mounted on top of the striker box and contains a free moving stud \( D \), and a free crank-shaft \( E \), between which the record roll is caught; a tracker bar \( F \) having on it one contact for each magnet; a comb \( G \) having one contact for each contact; and a receiving roller \( H \) for receiving the paper roll as it unwinds. The record roll is placed between \( D \) and \( E \) by pulling \( D \) to the left against the spring and placing the right-hand end of the roller against the screw-driver-like crank \( E \). The comb \( G \) is then removed from under the heads of its retaining screws by slipping it upwards and the end of the record led over the tracker bar \( F \) and fastened to the receiving roller \( H \), by slipping the ring in the end of the roller over the little hook \( J \). The comb is then replaced with its fingers bearing on the paper record and the receiving roller rotated slowly by turning the crank \( K \). Now when the holes in the paper record come under the fingers a contact will be made and the proper magnets will receive current and strike the proper keys. When the record is finished the comb is removed and the record re-rolled by means of the crank \( E \) (or by motor, if one is used for playing the piano). The tracker bar and the comb are mounted on an independent board, the construction of which is shown clearly in Detail No. 26. This board is arranged to slide sidewise in the main translator box for this purpose. The paper has a tendency to work over one way or the other on the tracker bar and thus tend to get the holes out of alignment with the comb fingers, causing imperfect reproduction, in which case it is necessary either to shift the record or the tracker bar. In this mechanism we shift the tracker board \( 24 \). This motion is usually very little and is tended to with the left hand on the knob \( M \). Reference to Fig. 5, at the right, will make clear how turning the knob one way will slide the tracker bar and comb to one side, and turning in the other direction to the other side.

(To be concluded)
Experimental Mechanics

By SAMUEL COHEN

LESSON III.

BEFORE the novice can begin to handle the lathe it is essential for him to remember that the lathe is an instrument of precision and that in working with the lathe, the operator must be guided by the rule that the ends and the parts of the machine must be handled with great care. The beginner should understand thoroughly, as each one of them is for a definite purpose. The amateur must also know how to sharpen these tools, in order that they may give the best results. All of these problems will be taken up in order.

The first thing that experimental machinists should see is that the lathe is running true. These are made of tool steel; the one in the revolving spindle is usually soft, because it turns with the work, which is hardened. The one at the tail stock is hardened. This is done because the article to be machined revolves on this center and causes constant wear. A good plan is to test occasionally the truth of these centers. In Fig. 1, a center is shown being tested for angular slope by means of a center gauge. It is very important that the end slopes to a 60-degree angle. In order to machine any round stock article between centers of a lathe, it is necessary to determine squareness of the centers on both sides of the article, then to drill and countersink each end so that it may revolve on the centers with ease.

There are several ways of centering a round piece, and of the simplest and best methods will be considered. The first one is to employ a combination square, as shown in Fig. 2, and carefully scratching across the face of the work with either a pencil, a scriber, or a countersink at right angles. The point of intersection of these two diameters will be the center of the cylinder. A center punch is set on the point of intersection and driven into the metal until a good indentation is made. This method will be found to be very useful and helpful, as it is the simplest and quickest method of centering a part. The combination square, and one can be bought for a nominal sum.

Another method of centering is to use the lathe itself. Fig. 3 shows how this is done. The article in question, A, is firmly secured in the live chuck of the headstock, B, and a drill chuck C, with a proper arbor, is secured to the spindle of the tail stock, D. A special centering drill 1 is secured in the drill chuck. By setting the main chuck holding the article and carefully bringing the centering drill to the face of the article, then gradually forcing the drill into the metal surface, it will automatically find the center and drill the hole and at the same time countersink it. Care should be taken to see that the drill does not advance too rapidly into the metal, as it might catch and break the drill. Sufficient oil should be poured on the drill when in operation. Another point to remember is to see that the article in question does not turn very fast.

These centering drills are very handy, and the amateur should not be without one, as they will be required very frequently. There are several sizes on the market and they can be bought in any reliable store carrying machinery supplies.

Accidents will happen now and then, and a center drill may break, part of the broken drill remaining in the shaft. This broken part should be immediately removed. Sometimes the experimenter may be able to work the broken part out with a chisel, but occasionally it sticks so hard it cannot be removed. When this occurs the broken part of the drill left in the shaft must be annealed; the only way to anneal it is to heat the shaft red hot and hold it there until it is entirely cooled off. It is then ready to be worked and the broken part can easily be removed. It is very important to note that every hole be properly countersunk if it is to be used between centers. The beginner will find it very advantageous to begin with the right method of countersinking and thus avoid breaking down or quickly wearing away his head center point. A very poor and improper way of countersinking is shown in Fig. 4. The center bears the point on the article without any bearing surface support. The article turns, and a load applied to the surface of the article by the cutting tool, the point would not be strong enough and thus breaks or goes off. This of course, results in a loss of time in resharpening or regrinding the center. The proper method of countersinking a hole for lathe work is delineated by Fig. 5. In this case it will be noticed that the portion bears firmly on the slope surface of the center and not on the point.

This method of countersinking is accomplished by drilling a small hole in the part where the center is desired and then countersinking it with a countersink having a 60-degree cutting edge. In other words, the countersunk portion should have the identical slope as the slope of the center of the lathe, which is also 60 degrees. It is well to remember that whenever you desire to turn a piece of work by means of the centers, see to it that its internal centers are clean, as otherwise the work will not run true or may damage the lathe centers.

If the amateur does not use a universal chuck on the live spindle for holding the work, a tool called the lathe dog will be found useful in connection with the face plate. The first photograph of the second installment shows how it is used, while Fig. 6 shows a common form of the lathe dog. The work is secured inside of the ring of the dog and firmly tightened in the same by means of the lock screw. The centers of the machined article are placed on the lathe centers while the bent portion of the dog is placed into any of the slots of the face plate. This will cause the work to turn when the live spindle is rotated by applying the driving power. There are several sizes of dogs on the market, and it is advised that at least four sizes should be on hand. The 1, 1½, 2½, and 3½-inch type will be found most satisfactory for the work which the novice will encounter at the beginning. The lathe dog cannot be used at all times, especially when a short piece of metal is desired to be machined. In this case a chuck is very helpful, and the amateur should not be without one. A 4-inch 4-jaw universal chuck with two sets of jaws will be found very useful.

The accuracy of the work will depend upon how accurate the chuck turns, and for this reason it is strongly advised that the beginner should not attempt to set the chuck on the live spindle himself, as a great deal of skill is required to do such a job. It is recommended to have a good machinist place the chuck on, if the chuck has not been directly purchased from the lathe manufacturers, who usually do this kind of work for the purchaser. The amateur has only to bring the original face plate with the chuck and its face plate to a machinist and have him fit it on. He has to properly thread the chuck face plate with the right thread, which he gages from the original face plate.

In using a lathe for cutting purposes, special tools are used for each particular
ELECTRICAL EXPERIMENTER

May, 1918

At running the tool post will be held without undue chattering.

When machining or dressing down a piece of cast iron it will be found that if a heavy cut is not made at the beginning that the surface soon of the cast iron, which is mostly sand, will ruin the cutting edge of the tool. It is advisable for this reason to take a heavy cut at the beginning so as to remove the surface scale.

The effective cutting on a metal will largely depend upon the degree of sharpness of the cutting edge and upon the manner it is ground. The tool should have plenty of clearance, a good rake and a clean cutting edge. The tool should be ground on a lathe or an emery wheel, which is running quite fast. The tool should be kept cool during grinding, and this can be done by immersing the tool into cold water every few seconds during the grinding process. After the tool has been ground on the wheel it is then well to dress up the cutting edge by hand with a small oil or fine carborundum stone. This will improve the wearing qualities of the cutting edge.

It is advisable that the novice should become a thorough master of the above facts, as they are the fundamentals to the successful operation of the lathe. If these points are observed, there is little chance of turning out a real good piece of work on the machine.

(To be continued.)

Diagram Showing How the Lathe Tool Should be Set with Respect to the Work Being Machined.

CLOCK NEWS.

By Thomas Reed.

The recent labor-flurry at the plant of a well-known clock company in Chelsea, Mass., recalls the interesting story that its

work the more firmly the tool post will be held without undue chattering.

Incorrect Center Support Correct Center Support

This Diagram Shows Clearly the Correct and Incorrect Method of Counterboring Stock to be Supported on a Lathe "Center."

ELECTROLYTIC TREATMENT OF LEAD POISONING.

Dr. L. G. Witherspoon, in Southwestern Medicine, gives his recent experience at a large industrial plant in the electrolytic treatment of lead poisoning. The method used is that of Dr. H. L. Jones of St. Bartholomew's Hospital, London, as perfected by Sir Thomas Oliver on the suggestion of T. M. Claude of that city.

Instead of immersing the patient in an electric bath, the outside bipolar system is resorted to. The patient sits on an insulated chair with the feet in a basin holding salt water, 15 grains to the pint, the hands in a similar basin, the positive wire going to the tool basin and the negative to the hand basin. A current of 16 volts passes for from 20 to 40 minutes daily or every second or third day depending on the severity of the case. Ordinary cases require at least 25 days. For prophylaxis one weekly treatment usually suffices. Severe cases with wrist drop or cerebral symptoms may demand treatment for 60 days or even longer.

The latest style of electric railroad crossing signal imitates the waving of a lantern or flag in the right hand exactly. The advantage of this lies in the fact that a moving light will attract more attention than a stationary signal.
“Shooting” Electrical Troubles on Automobiles

By THOMAS W. BENJAMIN

A rule the motorist just begins to realize that the electrical equipment of his car is subject to failure when he learns to ignore or crank the engine for the first time. Then the garage man is given a hurried call and,

more often than not, a call-down, when the bill arrives a little later.

Despite its seeming simplicity the electrical apparatus will respond to a little care and can be kept in the pink of condition if the little faults that develop are taken care of before they become large enough to cause any great trouble. For instance, it is not noticeable when one side of the battery becomes ground off; and the car may run in this condition for months, but, Ah! BUT—when the other side goes to ground it often means a new storage battery and perhaps an overhaul of the generator.

The instruments required to test the electrical equipment on the car from time to time is not costly, while it constitutes the best form of insurance one can buy. A voltmeter with a range of 0-10 volts, or 0-15 if a twelve volt system is used, and an ammeter reading 0-30 amperes, are required. Reliable small meters can be purchased for $5.00 to $8.00 each.

Test cords are required for the above meters. For the voltmeter cords, use single lamp cord, two 6 ft. lengths being cut. Fit one end of each cord with a lug to make connections to the meter, the other end having a prod made from a 6-inch length of % inch round iron rod. A suggestion for making the prods is given in Fig. 1. The cords for the ammeter are but two feet long and are made of double lamp cord, fitting one pair of terminals with lugs as in the previous case and the other ends with heavy spring test clips. Those with flat jaws are the best for the purpose.

A hydrometer is necessary, a dollar bill buys a good one— the writer has seen these on sale for a quarter, but purchase one fitted with a syringe—it’s much cleaner and easier to handle.

Altho not absolutely necessary a simple device for testing out circuits will be found

handy. The simplest form comprising a 75-ohm watch-case telephone receiver fitted to a head-band and a small two-cell flashlight battery taped to the inside of the headband, (Fig. 1). One post of the battery being connected to one terminal of the telephone, a set of 4- foot cords, fitting with small prods, are connected to the remaining terminals of the battery and phone. This completes the apparatus required. The various instruments are illustrated in Fig. 1.

We can now test any electrical equipment and locate the tiny faults that may sometime tie the car up on the road. And should trouble develop we can easily locate it. The prudent auto driver or owner always tests the electrical equipment before starting on long tours, and even before making long ones.

Motor Fails to Crank. Engine Runs Slow or Lights Are Dim.

Turn the engine over by hand to see if the bearings are not stuck. Take gravity reading on all the storage cells; this is a good indication of their condition.

If they have not been tampered with by some inexperienced person. The readings of the

cells should not vary more than twenty points and should be over 1.200. If below this the battery is discharged and should be charged at once. If the cells vary greatly in the reading locate the trouble. It may be due to a short-circuited cell, broken separator or high sediment.

The gravity is over 1.200 in all cells the battery should crank the engine and the trouble is elsewhere.

Take a voltmeter reading on the battery as shown in Fig. 2 the battery should read 6.5 volts or a little higher, with a 3 cell

battery; a 6 cell battery should be twice this. Should the voltage be below this figure and the gravity 1.200 it indicates that too much acid has been put into the cell.

With the voltmeter still across the battery, switch on the lights as in Fig. 3. There should be a very small voltage drop, if it is excessive it indicates a short-circuit on the wires that is draining the battery. Test each circuit independently to locate the circuit on which the short exists. By tracing the wiring the trouble can be removed.

Now have someone close the starter switch, if no trouble is located on the light circuits as in Fig. 4. The voltage may drop as low as 5.2 volts with a three cell battery and no trouble will be found. Should the voltage drop below this figure, the cells are low and need charging. When using the starter for testing, the switch should be kept closed long enough to take the readings for the drain on the battery is cumulative.

A test should now be made of each individual cell as in Fig. 5. Closing the starter switch after connection is made to each cell in turn. Should one cell or cells be lower than the other or others, it indicates discharge due to short-circuit, lost active material or defective separators. Should a cell give a reading, this may be due to the above causes or low electrolyte. A charge should be given the battery from some outside source or by running the engine if the generator is in operative condition.

Should the cells test O. K., attach the voltmeter leads to the cables of the battery as shown in Fig. 6. If a drop of voltage is noticed over that from the battery terminals, it indicates corroded or broken connections. Remove the cable from the battery and scrape off the corrosion, after cleaning thoroughly, rub the parts well with vaseline and reassemble, making sure that the connections are tight. Another test with the voltmeter should show no drop.

These tests practically eliminate the trouble from the batteries and attention should be turned to the other parts of the system.

The voltmeter should be connected across the terminals of the motor as in Fig. 7 and the starter switch closed for an instant. If there is a decided drop in voltage at the motor terminals over that at the battery terminals, with the starter on, the trouble lies in the wiring or the starter switch.

A test of the starter switch can be made as in Fig. 8, by slugging the voltmeter across it and closing the switch. A reading on the meter indicates a defective switch, usually

(Continued on page 69)
A Tight Squeeze for Uncle George

By THOMAS REED

I CAME near going on the stage once. Not to act, you understand—not as bad as that—but simply to show stage-managers a few things about their business. In the fresh springtime of my career, I never hesitated to butt, with a few pertinent suggestions, into any ancient or modern institution, and having, at the time of this tale, just made the acquaintance of the drama, as a means of livelihood, which had been plugging along quite a spell on scanty resources, I desired to give even that lowly calling a little attention.

The occasion was my Uncle George's taking me to the theater for the first time. In those days, people approved of the theater as heartily as they do of opium dens nowadays—that is to say, scarcely at all or less; but "Unc" had a theory that it was beneficial to make the Devil's acquaintance young, so he insisted (as much as he had to) on my going along.

We had to wait our step carefully, because a previous expedition of ours under his theory (I think it was a horse race) had caused unmistakable demur in the family. It made father almost impetuous. He said that while a peppy bachelor (Uncle George was such) might poison his own soul in any lot, so he saw fit, it meant a hell-sentence for him to lure innocent Youth into the clutches of the Evil One; and he went on to describe, for "Unc"s" special benefit, the warmth of that particular hell reserved for middle-aged republicans convicted of luring. This was before the invention of ferrets and oxy-acetylene, and the only fuel that Theology possessed, to get up steam for the sinners with, was "fire and brimstone." With the modern inflammables, father's imagination of hell would have made him such an extra hazard around the house as to vitiate our fire-insurance policy: but he did pretty well with even the old-fashioned chemicals. He did so well, anyhow, that Uncle George was the first called to take me to the matinee, thought it prudent to employ camouflage, and carried conspicuously two smell-poles and a can of bait, which he left in a vacant lot after they had created the desired atmosphere of innocence.

The "theater" that agitated the old folks so, meant plays like "Uncle Tom's Cabin," and "Ten Nights in a Bar-Room," that dripped, like a shirt in the wringer, with mortality and sadness. As even these dismal sketches were supposed irresistibly to skid the virtuous from the street and narrow path, a stupendous horror overspread the community when along in the eighties came the first "show" that actually aimed to be merry. "Good-night!" said the community: "so there was something worse, after all!"

This new show was "The Black Crook." Today, we should call it "Spectacle" and "Extravaganza," and let it go at that but to the elders, it was a moral catastrophe, without any special classification. They objected to it practically in toto, as the fellow who produced the fresh springtime of the play, or plot, because it was a down-right lie—not even "founded on fact," which at least you could say for Eliza's trip on the ice. And what did you think of the witches, and fairies, and men dressed up like animals? Didn't that give you false impressions of life? I should say so. Then, look at the dancers, and card-trick players, and actors that made believe intoxicated—all the forms of iniquity you ever heard of, and then some! But the most outrageous feature of all, the one mentioned with heaviest laced breath, was the tights. Would you believe it? Women—or beings in female form—actually came on the stage wearing nothing but—sort of stockings, you know, on their—their—well, what they wear stockings on?

It was only after "The Black Crook" had departed (it had quite a long run before all the sinners were accommodated) that my spiritual health was regarded as beyond danger.

But alas! (you get me?) it happened to conscience allowed me to reap the benefit of his misfortune. Several inventions occurred to me, so close together that they almost overlapped. I mentioned them to Uncle George, but the Amazons were marching, and he seemed preoccupied. Evidently the show as it stood was good enough for him.

The chief of these inventions was inspired by a beautiful blue light, studded with stars, which invaded the stage at certain intense moments. Something told me it was produced by a glass plate shoved in the front of the calcium light; the display being heralded by the magnified image of the chipt edge of the plate, followed by a flock of elephant-tracks, due to prints of the operator's fingers, stained by honest toil.

At the first sight of this spectacle the invention referred to burst upon me with that sort of Faradic shock familiar to inventors, particularly young ones. By the time it came again my apparatus was completed (mentally) to the last detail. By the third view I was storming the theatrical profession with it, and making lucrative contracts right and left; and the royalties were just about to pour in, when—the show was over, and Uncle George was suggest-
MAKING BATTERY 'PHONE SERVE AS "EXTENSION."

The subscriber who may desire one or more "extensions" must needs have the extra equipment installed by the 'phone company and must rent the added apparatus by the year or month, as the case may be. It is a comparatively easy matter, in a plant where private inter-communicating battery telephones are already installed or are about to be, to make the local 'phones serve as the "extensions."

For this purpose we need a very sensitive transmitter and this is recessed into a table or the top of the local telephone switch-board so that the mouthpiece stands flush with the table surface. A loud speaking receiver, properly connected with the sensitive transmitter, is mounted on a standard firmly attached to the top of the table, at such a height that the mouthpiece of the regulation desk 'phone set, when brought close up to it, is concentric with the diagram of the receiver. The arrangement is shown by the accompanying illustration. The regulation switch-board plug jack is used to connect the sensitive transmitter and receiver with the various extensions thru the medium of the switch-board. A block of wood, with a semicircular indentakes the base of the telephone set and insures that it stands always squarely in front of the loud speaking receiver.

Ordinarily, when not in use, the telephone transmitter rests on its hook in the orthodox manner. In establishing connections, between the regular 'phone and any one of the extensions, the operator plugs into the proper extension on the intercommunicating system, places the desk set squarely in front of the loud speaking receiver, and inverted the telephone receiver over the sensitive transmitter as shown, when communication is established with remarkably clearness. It is advantageous, but not essential, to have a regulation switch-board operator's head set and breast transmitter in circuit with the loud speaking apparatus so that the operator can listen in and correct errors.

SECOND PRIZE, $2.00

AN INEXPENSIVE BICYCLE LIGHT

Use an old pocket flashlight, size 1 x 2 3/4 x 3/4 inches which may have neither battery nor bulb. First cut the lower part of the case off, as here shown, leaving a smooth edge. Then from a piece of wood cut a block B so that it will just slip into the open end of the flashlight case. Next secure a clamp from an old bicycle bell shown at C. Bore a 3/8" hole from F to C and put a small machine screw thru and countersink the nut in the other end of the block at F. Then take a piece of steel battery screws and put thru the block at D. E, a round head brass screw is put in the end of the block and connected to bolt D' by a copper wire, while bolt D is connected to the clamp and bolt C. Slip the case over the block and tack on both sides or glue it to the block. Remove the cap of the bulb and connect to the base of the flashlight case for the battery.

AMATEUR ELECTRICIANS!

ATTENTION!!

Did you read the prize contest article entitled "Utilizing Burnt-out Lamp Bulbs," which appeared in the April number of this journal? If not, procure a copy to-day. Here is your chance to make some money. Prizes are offered for the best ideas—What to do with burnt-out lamp bulbs—and prizes will be awarded as follows: First prize, $3.00; second prize, $2.00 and third prize, one year's subscription to the ELECTRICAL EXPERIMENTER. Get busy, boys, and watch for the June issue.

A Nifty Electric Bicycle Head-light is Easily Constructed From an Old Pocket Flashlight in the Manner Illustrated.

holding the lens and you will see that when push button is drawn back, the metal strip touches the screw E and connects it-with the metal case of the flashlight, also that the end of the bulb will touch the end of the bolt and thus make the circuit thru the bulb from the two binding posts D and D'. Next buy a 2.5 volt flashlight bulb which can be obtained from any electrical store. The lamp case may then be given a coat of black enamel. The two dry cells (they do not have to be new as it will burn on partly used ones) required may be fastened to the stem between the front fork and the handle bar and the block D with a strap wrap around them and the stem and allowed to rest on the bar running down to the cranks. They should be connected to the lamp on the handle bar with flexible wires so that it will not break when turning corners.

Contributed by DONALD WILSON.
TO RENDER WATER SURFACE PHOSPHORESCENT.

1. Wet a lump of loaf sugar with phosphorized ether, and throw into a basin of water; the surface of the water will become luminous, and glow beautifully in the dark. By gently blowing upon it, phosphorescent undulations will be formed, which will illuminate the air above the fluid for a considerable space. In winter the water can be blood warm.

2. To melt a coin in a nut shell.—Mix three parts of dried niter, one of sulfur, and one-fourth of dry sawdust and press into a walnut shell, also inclose within the shell a piece of silver or copper, then fill the shell with more powder and set fire to it. The metal will soon be melted while the shell will be merely blackened.

3. The alchemists' dyes.—Dissolve indigo in diluted sulfuric acid, and add to it an equal quantity of solution of carbonate of potash. If a piece of white cloth be dipped in the mixture, it will be changed to blue; yellow cloth in the same mixture will be changed to green; red to purple; and blue litmus paper to red.

4. Two solids make a liquid.—Rub together in a mortar equal quantities of crystals of Glanbers salts and nitrat of ammonia, and the two will slowly become a liquid.

COPPER PLATING.
To copper plate a small steel object proceed in this way: Put 1/2 teaspoonful of sodium bisulphate in 1/2 glass of water.

Now add 1 1/2 teaspoonful of azurite. Heat gently to dissolve the substances. Dip the article that is to be plated into the solution and leave it for about one-half minute, and dry on a cloth.

Test to Determine the Freshness of an Egg. Put 2 teaspoonfuls of common table salt into a pint of water. A fresh egg placed in this solution will barely float. The greater tendency of an egg to float on the surface the older it is. This is due to the fact that as an egg decomposes it becomes lighter.

Nitrogen Monoxid.

THIS gas, which is also known by the names nitrous oxid and laughing gas, was discovered by Priestley in 1772. Preparation.—The usual method of preparing this gas is by heating ammonium nitrat and collecting the dissociated gas over water. This relation is shown by the following equation:

\[ \text{NH}_4\text{NO}_3 \rightarrow \text{N}_2 + 2\text{H}_2\text{O} \]

Properties:—1. This is a colorless gas, producing a faint peculiar odor, and sweet taste.
2. It produces anesthesia.
3. It is a supporter of combustion. It supports the combustion of many substances as actively as does oxygen.
4. When mixed with hydrogen it is explosive when ignited.
5. It has been liquefied under ordinary atmospheric pressure, requiring —88 deg. It may be liquefied at 0 deg. by a pressure of 20 atmospheres.

As a liquid it is colorless and very mobile, boiling under ordinary pressure at —89.8 deg.

Uses:—This gas (Nitrous oxid) is extensively used by dentists in extracting teeth, where a short anesthetic effect is desired. It is obvious that for this purpose the gas must be perfectly pure. The greatest safeguard to obtain the pure gas is to employ pure ammonium nitrat, the chief impurity of which is ammonium chlorid. Ammonium chlorid if present would occasion the presence of chlorin in the gas. For the preparation of the gas for anesthetic purposes, it is past thru three wash-bottles, one of which contains ferrous sulfate solution which removes the other secondary oxides of nitrogen formed thru secondary decomposition; one of sodium hydroxid solution to remove the chlorin; and lasty one of pure water.

When mixed with air or oxygen the gas produces a condition of partial insensibility in which the patient becomes hysterical, laughing immoderately, hence the name “laughing gas.”

EXPERIMENT NO. 123. Preparation of Nitrogen Monoxid from Ammonium Nitrat (NH_4NO_3).

10 grams of ammonium nitrat into a plain thin glass Erlenmeyer or Florence flask of 250 cc. capacity. As a precaution of not breaking the glass, put in not over 1 cc. of water in 1-2 stopper (rubber) carrying a right-angle delivery tube leading just thru a two-hole stopper in an empty 8 ounce bottle, from which another tube leads to a trough with inverted bottles filled with water. See Fig. 114. Set the apparatus on an asbestos pad over a tripod, or on the ring of the ring-stand, and apply at first gentle heat, which may afterwards be increased, but the action should not be permitted to become too vigorous. If necessary, take away the lamp, temporarily. As usual, the first portions of the gas to pass over the delivery tube should be rejected. If there is any evidence of lack suction of the water from the trough to the bottle, disconnect the stopper in the latter for a minute.

After collecting about four jars of the gas, take away the lamp and at once either loosen the stopper in the bottle or take the delivery tube out of the trough. When you disconnect the apparatus thrust a lighted splint into the gas in the flask. Note the phenomenon. When the flask is cool enough to permit being handled, pour in water thru a funnel and dissolve the residue. Test the gas that has been obtained. (See following experiments.) If a liquid is in the intervening bottle, test it with litmus. This gas is commonly called nitrous oxid; by dentists simply gas.

EXPERIMENT NO. 124. Properties and tests.

Note whether the gas in the various bottles is clear or mixt with some visible impurity. If it is impure, note any variability in that collected under greater or stronger heat. Try and determine whether such impurity is of a solid or gaseous nature. With a glass plate (as described in the Lesson on experiments with Oxygen) take one of the jars from the shelf or tray, try the odor of the gas, and then test it with a glowing splint several times, and keep the product, that is the gas which is obtained after the introduction of the splint, covered to prevent escape.

What gas does it resemble in its combustion test? In that case what do you suppose the product to be? Formulate a test for the product which you surmise, and apply this test to determine whether your conclusion is correct. If you were wrong try and find out just what the product is.

Try the action of burning sulfur in another receiver of nitrogen monoxid, using a carbon cup in the customary manner.

Nitrogen Monoxid and Oxygen. Nitric Oxid Test.

As nitrogen monoxid, (or nitrous oxid (N_2O_3),) acts very much like oxygen, especially in regard to combustion, it becomes necessary to distinguish the two gases. The following experiment gives a simple method:

Prepare two bottles of nitrous oxid (N_2O_3) (preferably in separate trays or troughs), by the action of Nitric acid on copper. Prepare also an oxygen generator (See Lesson on Oxygen) using potassium chlorate and manganese dioxid, and let the oxygen bubble up into one of these receivers filled with the nitrogen dioxid. Continue the operation as long as necessary, to determine the nature of the result. Notice any phenomena which are occasioned.

Then generate nitrogen monoxid (N_2O) (Continued on page 54)
"Electrical Laboratory" Contest

In the March issue we publisht an interesting story with a number of excellent photos, describing one Amateur Electrician's experimental laboratory. Now "Bugs"—we want to publish similar articles each month. Here's our proposition: Why not write up your "Electrical Lab." in not more than 500 words. Dress it up with several good, clear photographs. If we think it good enough we will publish the article in display style and pay you well for it. The remuneration for such articles will range from $5.00 to $10.00. And "Bugs"—don't forget to make your article interesting. Talking about Radio Amateur activities, we wish to mention the "Prospect Radio Club" of Brooklyn, N. Y., whose picture is reproduced herewith. Here's the right idea, "Bugs." A course in Radio was started last October, with the object of training the members to take the First Commercial license examination. Lectures, which are part of the course, are illustrated by projections and experiments. A practise class has also been started in conjunction with the course, to get up a speed of at least twenty words per minute. The officers for the term are as follows: President, L. Jacquet; Vice-President, Mr. C. Hild; Secretary, Mr. W. Benson; Treasurer, Mr. D. Langan. The Club would like to hear from other Brooklyn clubs, and welcomes visitors to their meetings. Address all communications to the Secretary, Mr. W. Benson, No. 4 Fuller Place, Brooklyn, N. Y. Get ready to help your Uncle Sam!!! Send all laboratory photos to Editor "With the Amateur's Prize Contest."

A GROUP OF REPRESENTATIVE AMERICAN AMATEUR LABORATORIES.

Magnetic Sander for Autos (1,257,305; issued to Bridge N. McCallum.)

A semi-automated sanding device for use on automobiles and similar vehicles. A simple switch mounted on the dash within easy reach of the driver, connects with a storage battery and two solenoid controlled sand box valves as shown. One solenoid and valve is placed on each side of the car, the sand box being placed under the rear seat. Also there are provided two nozzles which swing downward toward the road-bed whenever the magnets are operated and sand released thru the valves. A coated contractile spring normally holds the sand valves shut and the nozzles to a neutral position.

Combined Rotary Gap and Motor (1,250,385; issued to C. H. Troll.)

Combination invention relating to a gap used in radio-telegraphy, together with rotating motor drive of the gap, the stator of which is located within and concentric with the rotary gap member and thus the latter may be driven at any suitable speed by the motor embodied within the device. The motor is adapted to be operated on battery power. The poles of the motor are wound with coils of wire, as well as those of the stator, the direction of the current thru the respective windings being periodically changed by means of a commutator.

Talking Condenser (1,257,092; issued to J. W. Fuller.)

An improved form of voice reproduction apparatus operating on the principle of a condenser. The talking unit proper is composed of a number of sheets of tin-foil interposed between a number of oil-silk or similar dielectric material, connecting the alternate foil sheets to opposite sides of the exciting circuit. The inventor proposes a talking condenser made up of 100 sheets of very thin tin-foil interposed lightly, so as to be free to vibrate between an equal number of smooth paraffin paper, each sheet being denser, an induction coil, and a source of variable primary current as produced by a telegrapher, etc.

A novel patent on an illuminated spark gap frame to be worn by a person doing special work and intended to enable the person to see the work clearly, without eye-strain. Also both hands of the wearer are free to operate. A hollow socket in the glass case thru which the center of the lamp is provided, a dark sleeve inside the passage of the lamp enabling the user to see the object clearly. The eyes are said to be further protected from over-straining by limiting the view thru the openings. Provision is made for using colored lamps or colored screens when desired.

Mineral Detector Stand (1,257,526; issued to G. W. Pickard.)

An improvement in constant-pressure solid rectifiers, in which the adjustment of pressure of the contact point on the mineral is effected by a balanced bar, similar to a scale. Among other superior features claimed for this form of crystal detector stand are: Increased rectifying efficiency of practically all solid rectifiers, greater stability and adjustment and of accurate duplication of pressure adjustment. Galena is cited as one of the minerals wonderfully improved by the apparatus, reaching an efficiency unattainable heretofore in spring contact detector stands. No account of its low degree of stability and its great difficulty of adjustment. The number of operative contact points on the galena or other mineral is greatly increased with this constant-pressure contact.

Spark Gap (1,256,405; issued to Harlan S. Webster.)

An improved form of spark gap intended for radio or X-ray requirements. It is made in the form of a rotary blower as shown, thus creating a powerful cooling effect. Another object is to provide in such an apparatus means whereby the sparks produced will be of uniform length. The stationary electrodes are aligned with and in proximity to the revolving electrode, each station.

Talking Picture Control (1,254,436; issued to H. W. Rogers.)

A new method of producing talking motion pictures, especially the synchronization of voice apparatus with the picture projector. The device is applied to the magazines of the motion picture projectors now in use. The film in the present instance is past around a rotating drum which is provided with a plurality of sliding pins. As the drum revolves with the film, the pins are projected thru openings in the film, and thus brought into contact with a switch closing device. This switch, in coaction with the perforations in the film, is thus caused to synchronously control one or more sound reproducers, such as phonographs. The drum pins are projected radially outward by gravity, aided by a magnet.

Wireless Telephone (1,236,354; issued to Walton Harri son.)

A unique wireless telephone employing a usual complicated apparatus is dispensed with. Instead of using an arc or other recognized form of radio-frequency oscillation generator, Mr. Harrison makes use of a special microphonic member, connected up as shown. Ordinarily no auxiliary condenser and inductance are necessary in the operation of such apparatus. The capacity and inductance of the apparatus serving two purposes. The hook-up delineated is suitable, the inventor states, for both transmitting and receiving speech or music. Suitable coils are provided. Very low voltages are available in this system. Oscillations are set up due to the inherent instability of low-resistance microphonic devices. The microphone also acts as detector.
Phoney Patents

Under this heading are published electrical or mechanical ideas which our clever inventors, for reasons best known to themselves, have as yet not patented. We furthermore call attention to our celebrated Phoney Patent Office for the relief of all suffering daffy inventors in this country as well as for the entire universe. We are revolutionizing the Patent business and OFFER YOU THREE DOLLARS ($3.00) FOR THE BEST PATENT. If you take your Phoney Patent to Washington, they charge you $20.00 for the initial fee and then you haven't a smell of the Patent yet. After they have allowed the Patent, you must pay another $20.00 as a final fee. That's $40.00! WE PAY YOU $3.00 and grant you a Phoney Patent in the bargain, so you save $43.00!! When sending in your Phoney Patent application, be sure that it is as daffy as a lovesick bat. The daffier, the better. Simple sketches and a short description will help our staff of Phoney Patent examiners to issue a Phoney Patent on your invention in a jiffy.

Prize Winner, ELECTRIC QUILT REVERSER. Remember Those Bitter Cold Winter Nights When You Woke Up at 12 G. M., With Nothing On You But Your Night-gown? These Frigid Experiences Are Now Gone Forever, Thanks to My Wizard "Electric Quilt Reverser." If Wifey (or Hubby, If He Gets the Preferred Position First) Awakes and Finds the Other Branch of the Family Tree All Cozied Up in the Only Six Blankets in Sight—Presto! the Said Victim Simply Has to Press a Button—the Electric Motor Starts Up and Whirls the Blanket-Hog Until His (or Her) Ideas Are Separated From His Bad Habits. Inventor, Paul Patterson, Elgin, III.

Electric "Comfy Chair." The Days of the Old Man's Club Are Numbered, for Behold the Latest Electrically Equipped Club Chair! It Is Equally Efficient in a 2 x 4 Harlem Flat, for Which a Special Collapsible Style Has Been Invented, or At the Seashore. It Keeps Battery. This In Turn Runs a Motor for Rocking the Chair, as Well as Supplying Current for the Electric Cigar Lighter, Fan, Book Holder, Back Scratcher, Et Cetera, Ad Lib, Ad Infinitum. It's Great, Boys, Try It! Inventor, Le Roy Nisbet, Battle Creek, Mich.
THE ORACLE

The "Oracle" is for the sole benefit of all electrical experimenters. Questions will be answered here for the benefit of all, but only one answer will be published. Rules under which questions will be answered:
1. Only three questions can be submitted to be answered.
2. Only one side of sheet can be written on; matter must be typewritten or else written in ink, no penciled matter considered.
3. Sketches, diagrams, etc., must be on separate sheets. Questions addresed to this department cannot be answered by mail free of charge.
4. If a quick answer is desired by mail, a nominal charge of 25 cents is made for each question. If the questions entail considerable research work or intricate calculations a special rate will be charged. Correspondents will be informed as to the fee before such questions are answered.

2-INCH SPARK COIL DATA.

(918) Geo. A. Detrick, Vinton, Iowa, inquires:
Q. 1. How to wind a two-inch spark coil.
A. 1. To build a two-inch spark coil, use an iron core made of soft iron wire about 7 inches long and ¾ of an inch in diameter, upon which wrap two layers of Empire cloth. Now wind on two layers of No. 16 B. & S. double cotton covered magnet wire which is approximately 190 turns. Over this primary, wrap 6 layers of Empire cloth, and wind on the secondary in two sections, with No. 30 enamelled magnet wire, ½ lbs., of which will take care of the sections very well.
The primary condenser should consist of about 1,400 square inches of tin-foil, interleaved with paraffined paper. The connection should be as per diagram.

CONDENSER TROUBLE.

(919) J. C. Muirhead, Nova Scotia, Can, asks several condenser questions.
A. 1. We would advise that in building a glass plate condenser, where the lugs were omitted, i.e. the tin-foil was merely cut to the desired area, the best way to connect the lugs to the condenser so that the condenser when completed can be immersed in oil, would be to simply cut some extra strips of tin-foil and lay one strip on each piece of tin-foil already cut. These should be of sufficient length to protrude from each end; proceed to make connections with the protruding foil tabs.
Concerning your glass plate condenser, which has been built in three sections; when one section is connected to transformer, the spark obtained is O, K, but when three are connected to the transformer the plates are apparently punctured. The reason for this cna only be that in one or more of the condensers the insulation is defective at some place. Therefore, the best remedy is to connect the three condensers one at a time, and see if proper results are obtained.

MICROPHONE "PACKS."

(920) Win. J. Murdock, Clinton, Ind., says:
Q. 1. I have a microphone which fails to release a relay connected to it as soon as voice waves cease. How can I remedy this? A. 1. We believe the trouble you are having with your transmitter is due to the use of carbon grains, which are enclosed in the transmitter chamber. The only method by which you can perform the functions of which you speak in your question is by employing a direct contact transmitter. Such a type has been devised.

ODD PHOTOS WANTED AT $1.00 EACH!!!

Now is the time to make your Kodak pay for itself in a real practical way. We want interesting photographs of out-of-the-ordinary electrical, radio and scientific subjects and are willing to pay $1.00 cash for every one we can use. Please bear in mind that for half-tone reproduction in a magazine, a photograph should be particularly sharp and clear. Of course, if a subject happens to interest us particularly well, we can have the photo retouched. For the general run of subjects, however, it does not pay to go to such expense. Therefore, please take pains to properly focus and expose your pictures. It often happens that a really mediocre subject well photographed wins approval over an excellent subject poorly photographed. And don't send us plate or film "negatives"; send unmounted or mounted "prints" preferable a light and a dark one.
As to what to photograph: Well, that's hard for us to say. We leave that up to you, and every reader now has the opportunity to become a reporter of the latest things in the realm of Electricity, Radio and Science. But, please remember—it's the "odd, novel or practical item" that we are interested in. Every photo submitted should be accompanied by a brief description of 100 to 150 words. Give the "facts"—don't worry about the style. We'll attend to that. Enclose stamps if photos are to be returned and place a piece of cardboard in the envelope with them to prevent mutilation. Look around your town and see what you can find that's interesting.
Address photos to—Editor "Odd Photos," ELECTRICAL EXPERIMENTER, 233 Fulton Street, New York City.

THermo-COpLueS.

(921) M. Lompi, Albany, N. Y., asks:
Q. 1. What are the thermo-couples that will answer the Peltier effect?
A. 1. All thermo-couples will exhibit the Peltier effect, which is made evident in the following manner: In any thermo-couple where the junctions are of different temperatures, currents of electricity will flow in the circuit, which involve the expenditure of energy as heat, according to Joule's law, and there will be an increase or a decrease of the current in the circuit depending upon the direction of the flow of the current in the main. Heat developed due to the Peltier effect varies directly as the current produced, which differs from the heat developed in any other electrical circuit, in that the heat developed varies as the square of the current.
Q. 2. How are thermo-couples made?
A. 2. Thermo-couples are easily made by simply heating dissimilar metals at their junctions. The thermo-electromotive-force increases with the increase of the temperature, within certain limits.
Q. 3. What book treats on their action?
A. 3. We recommend the "Elementary Lessons in Electricity and Magnetism," by Sylvanus P. Thompson, supplied at $1.50 net.

STEP-DOWN TRANSFORMER.

(922) J. W. Fickler, Mason City, Iowa, inquires:
Q. 1. Hook-up and kilowatt-hours consumed by a certain step-down transformer.
A. 1. When you are obtaining an output of 25 volts and 25 amperes, the transformer will be drawing about 62½ amperes, and when you are drawing 25 volts and about 30 amperes the transformer will be consuming about 13 amperes. When the transformer is giving such a transfer of 25 amperes it consumes about 72½ of a kilowatt-hour, and when it gives an output of about

50 amperes it takes about 1.44 kilowatt-hours.

We give herewith a diagram of correct connections if such a transformer is used:

(The Light and Heavy Lines Show the Relative Voltage Proportions in a Step-down Transformer. As the voltage at the Secondary, the Current Increases, So That the Watts Remain Almost the Same.

I Will Teach You Electricity Practically—Thoroughly—Quickly

A. W. WICKS, Bach. Sc. E. E.
formerly with the General Electric Company; former General Manager of company manufacturing Jenney Electric Motors; also formerly with Fairbanks, Morse & Co.; now Consulting Engineer, President and Director of the Wicks Electrical Institute.

Personal Instruction By Mail

I have already helped hundreds to get out of small-paying, no-future jobs. C. A. Walker says: "Wicks training more than doubled my pay." E. Vogel says: "Am successfully installing electrical systems." O. Clausing says: "Offered a fine position." J. Obeso says: "Have a chance to run trolley systems by mail, just as I can give it to you. While you are drawing your present salary I can prepare you for a good electrical job or for a business of your own. Say to yourself now—'I will do it'—and then send the coupon now.

What You Can Earn

You know what good electricians make. If you are not sure that this is a paying business, look into it. Find out what salaries electric light and railway superintendent, telephone engineers, dynamo and motor experts and other electric men draw. See how busy every electrical contractor and supplier is. Are you doing as well as these men? Is not, why don't you get started? Look ahead. Take advantage of circumstances which have created this big present demand for electricians.

When I say that you can make a good income from electricity, I say just what you know yourself. I don't promise that you are going to step into $800 a year—and any school which leads you to think that every man who trains in electricity can earn such an income as that is going beyond the limit of reason. Some electricians do make that much and more but they are above the average—So don't accept big promises. Get the facts.

What I promise is to give you a thorough, practical education in basic principles and in the methods followed by the best electricians. I will give you my personal instruction, step by step, until you graduate, and afterward if necessary. I know from what my graduates report that, unless you are making over $25 a week with good prospects for a raise, you can study electricity to big advantage. There is all the opportunity in this field that any ambitious man can ask for. If schools which promise $1000 salaries can really help you to earn that much—surely this training ought to put you in line for even more.

Pay As You Learn. There is no big amount to pay at any time. Only a small payment down and a little each month pays for the course. I'll be with you at every step.

FREE Personal Analysis

Before you enroll, I ask you to fill out a Personal Analysis Sheet which enables me to tell just how well qualified you are to take up Electricity. Upon receipt of this I will advise you frankly whether to enroll or not. This enables you to know just what you may expect to gain from this course. No charge for this service, and no obligation upon you.

Send Coupon for Opportunity Book and Special Personal Analysis

If you are now in an occupation that promises only the ordinary or a doubtful outlook—if you are now an electrician ambitious to make quicker advancement, to better income—send without fail for this important book and Personal Analysis Report. Find out about this course. See what it offers. Let Prof. Wicks explain his method of teaching. Learn how you can put yourself years ahead by his personal instruction sent right to your home. The book, the Personal Analysis and all this information sent free. Also information on the easy monthly terms which puts this course easily within your reach. Don't put this off. No obligation or promise on your part. Send the coupon now.

SUBSTITUTE FOR PLATINUM.

(923) R. B. B., New Jersey, asks:
Q. 1. Several questions relative to a substitute for platinum, particularly a com-

position known as "Densite."
A. 1. Relative to "Densite" as a substitute for platinum, we would advise that if it stands up to the tests mentioned by you it is certainly a good substitute for platinum.
We would further say that platinum is universally used wherever its best qualities are desired, and that consumed for the purpose amounts to a very large quantity yearly. There are, however, other materials on the market that are substitutes for good contacts, such as silver, tungsten, steel, etc. Therefore, a proposition wherein an excellent substitute for platinum is had at 10 per cent of the prevailing cost of platinum is really a very good one, we should say.

HEATING COIL OPERATED ON BATTERY.

(924) M. O. Dellingcr, Wolcott, Ind., asks:
Q. 1. Can I produce one thousand degrees of heat in the hollow core of a small coil operated on a six-volt storage battery? How much wire, what size, and kind shall I wind it with?
A. 1. We would make our estimation of a temperature of the intensity you state from a six-volt storage battery for any considerable length of time.
However, a copper wire made out of constanti wire, No. 24 gauge, and if about fifteen feet of this wire is wound into coil form, it can then be employed for producing a high temperature of about the intensity you desire.

ELECTRO-MAGNET QUERY.

(925) Jos. Macowick, Ravenna, Nebras-
ka, writes the "Question Box":
Q. 1. Would a soft iron plate 4 x 4 x 3/4 inches, secured on one end of an open-core electro-magnet increase its pull?
A. 1. A soft iron plate, measuring 4 x 4 x 3/4 inches, if secured on one end of an open-core type electro-magnet, will increase the attractive power at the opposite end of the electro-agent considerably. This is due to the fact that in this way the reluctance of the external magnetic circuit of the electro-magnet, or in other words, you have provided an iron plate for part of the flux, which otherwise would have to complete its circuit thru the air from one end of the core to the other (see cut herewith). The air return circuit presents a very high reluctance to the magnetic lines of force. The most efficient type is the closed core solenoid or electro-magnet, in which an iron yoke return circuit is provided.

RESEARCH AND ITS IMPORTANCE TO HUMAN PROGRESS.

(Continued from page 19.)

ble increments which any producer may achieve. Do not think due research will lead to new knowledge. I want to illustrate.

Sometimes, somewhere, centuries ago, the slag of a furnace appeared transparent; some one tried to learn more about it, and so, ultimately, glass was made. Research is still under way on that very material, and numbers of useful additions have been added to the knowledge. Glass has kept the cold from the house. It has let in the light. It has renewed our eyes as they have worn out. Thus telescope and museum hope it has shown us the greatest and the smallest things of the universe. It has bottled our drinks and held our lights. Every year still adds new service, just as experiments add new knowledge. Today we hear of a new glass permeable to ultra-violet light, glass opaque to X-rays, and glass for cooking utensils. Not one of these little increments will ever be lost, but will continue in use, so how highly should we value them? A dilator delay so long in coming thus far, and how far or fast may we still go?

Research presents a way, and not the only one, of insuring peace, of preparing successfully for defense, and of being successful in war. It is the lasting, undeviating factor that always dominates. This may sound bold and entirely extravagant in itself. It is all true. Can we learn to see it? From the military expert to the peacemaker, this unerring instrument for over 100,000 years has been almost continuous on every continent. The inventors of chip flint successfully fought those inferi ors who had not experimented with that. There were then no better arms. These also got their game even when it was scarce and other means failed, and so they still added to survival. The early example of survival was repeated a great many times before our present complex conditions were reached. You can surely continue to be repeated. The fundam entals were always the same. A 42 cm. gun is only a better flint. Trinitrotoluol is only a modern nitrocellulose. War and ammunition have changed, but just so have also changed the myriads of other important accessories to survival. This is the imp ortant point. Let us not be bound by our clothes, and niter is good for fertilizers and for guncotton. The signs that we are improving in our civilization will also indicate that we are growing more in our national defense, but this should come rather as a consequence than as an object. The world has always been improving and the real growth and development has come to those nations which have been responsible for the original research work and not for the mere storage or conservation of the knowledge.

As a means of illustrating how one thread of work starts another, I will briefly rev iew part of a single fairly connected line of work in our laboratory. In 1901 the meter department wanted electrically con ducting rods of a size in the industry. These were to be one-quarter inch diameter by one inch length. We learned how and what to mix to get a porcellain, and we made small quantities of carbonium or of graphite would give us the desired resistance once in a hundred trials. The rods could be made, but the variation of these rods was taken from the porcellain kiln, and when they were made as nearly alike as we could make them, was often a thousand fold that something new had to be done to make a practical success.

(To be concluded.)

$70.00 for $15.00!!

Amateurs! Experimenters!! Opportunity Extra-Ordinaire!

Size of machine 19½ x 9½ x 8¼. Net weight 18 lbs.

These 3 tapes show how machine works

STATEMENT BY MR. H. GERNBACK, PRES.

"I have carefully read all the statements contained in this advertisement. Every word is true; nothing has been exaggerated. I believe this to be the greatest bargain,—the greatest value—that has ever been offered by my company to amateurs and experimenters, in its 14 years of existence."

HISTORY

The tape recording and perforating machine here illustrated and described is regularly manufactured by one of the largest electrical companies in the U. S. Some time ago a western telegraph company ordered a goodly quantity of these machines for their regular requirements. As we understand it, they paid over $70.00 apiece for these recording machines. The machines were duly shipped West by Express, but the telegraph company having financial troubles could not pay the heavy express charges. Thereupon the machines were returned to New York with added charges, and were finally sold at auction by the express company to recover the transportation charges, as is customary. We bought the entire lot of machines.

DESCRIPTION

This is a standard commercial, large size, perforating, telegraph recorder. It is exactly the same machine as used by the Western Union and Commercial Telegraph Companies in their main offices. This machine requires a double contact (back stop) telegraph key and a few batteries. Pressing the key operates in turn the two sets of powerful electro-magnets, which on their part operate the two ratchet wheels. These then operate two plungers which punch the holes in the tape (as illustration of tape). Since sending Morse code, the holes are punched in a certain manner. Then by feeding the tape back thru the machine and by arranging two brass contact fingers, the tape will spell out dots and dashes by means of a buzzer.

This machine has a truly wonderful spring motor. It is absolutely silent and has a centrifugal regulator speed-adjuster and stop arrangement. At the highest speed the motor runs 18 minutes, at the slowest speed 65 minutes continuously. Over all dimensions of machine are 19½ x 9½ x 8¼. Diameter of holes punched 1/16". The width of paper tape is 1/4". Aluminum reel 4½" diameter. The magnets measure 1½" x 2" and are 1½" thick. The net weight of the machine is 18 lbs. Our illus. shows machine with cover removed to show motor. The small insert shows the beautiful tandem electro-magnet arrangement, the ratchet wheels and perforating equipment. All wood work is solid mahogany.

USES

What you can do with this beautiful machine:

1ST—USE AS A PERFORATING MACHINE as already described. By means of a block of wood and a few bits of brass (or you can mount them on the base of the machine) you have a regular Morse sender and receiver. You can then ask a good operator to send a long message and you can listen to the dots and dashes as often as you wish. The tape record thus prepared will last a very long time.

2ND—AS A REGULAR MORSE REGISTER. With instructions which we supply and by using only two magnets (instead of 4) and by making a few slight changes, which any experimenter can do, the machine will write regulation dots and dashes on the tape. A pencil lead is used to do this. You can then bind an autograph to the recorder, and you are now enabled to read the messages by sight. Or you can send the message yourself with an ordinary key, etc., etc.

3RD—AS A SPECIAL REGISTER. By utilizing all four magnets a special type of dot and dash can be sent (as used in cable telegraphy). See sample of writing on the tape just leaving machine, above. This record can be read just as easy as regulation dot and dash (the dot is represented by the π sign). To send such signals a slight change is necessitated which can be made by any experimenter handy with tools.

4TH—AS A TELEGRAPHONE. Every experimenter has long wished for a real telegraphone, whereby the voice is recorded on a thin steel wire, and then reproduced over a cheap style 15 ohm pony telephone receiver. By means of this machine a very efficient telegraphone can be built by any experimenter handy with tools. No expensive extras are needed; a few bits of brass and steel will do the trick.

We furnish Blue Prints and full Directions to make all the above apparatus using the recorder. We also furnish 3 paper reel tapes, standard size.

Since does not permit listing all of the many good points of the recorder. Suffice it that the machine is the most expensive commercial type, with everything of the very best.

A similar machine is listed at $100.00 in the catalog of the Western Electric Co., a large company. We believe that the price of $15.00, below the ridiculously low price of $100.00, has never been equalled, nor can it possibly be met.

We have not a very large quantity of these machines on hand as we know that there exists a big demand for this recorder, we are almost certain that we will not run this "hot" machine. This is your one chance—each is while the machines last—you will never see such a bargain as long as you live—we are quite certain of it.

The size of the machine being 19½ x 9½ x 8¼; the net weight 18 lbs. (receiving weight 5 lbs.) it is necessary to ship it for express or freight. We guarantee immediate shipment within 24 hours after receipt of remittance. Order at once—today!—you won't regret it. If you live far away you may wish to send your order to the Electro Importing Co., 231 Fulton St., N. Y. C., and we will hold one or more machines awaiting your remittance.

Price as described complete $15.00

THE ELECTRO IMPORTING CO.

231 FULTON ST., N. Y. C.

"Everything for the Experimenter"
ELECTRICAL EXPERIMENTER

U. S. NEEDS MEN FOR SEARCH-LIGHT REGIMENT.

An excellent opportunity is being offered to young men possessing a knowledge of electricity and mechanics, as well as experienced electricians and machinists, to serve the Government effectively in its fight for democracy.

The War Department is organizing a regiment of searchlight companies for special service. These units will be highly specialized and used for battle illumination and anti-aircraft protection. The companies will be armed and equipped with regular military units and will form part of the regular army organization. They will be called upon for extremely active work in the war zone, and points are being taken in the selection of the personnel of the companies.

WHO CAN QUALIFY?

Men of proper experience who already have been drafted into service may in special cases be considered.

The plan is to obtain bright, young, intelligent and ambitious men between the ages of eighteen and twenty-one, who possess a fundamental knowledge of electricity and mechanics, as well as the experiences, qualifications and conditions found in electricians, gas-engine operators and machinists. The enlisted personnel will embrace men experienced in one or more of the following electrical specialties: (1) engine operator, machinist, motor-track driver, blacksmith, horesher, mechanic, and general labor.

Men must first enlist as privates and will be paid thirty dollars per month, together with food, clothing, medical attention, etc. Non-commissioned grades will be at rate of pay fifty dollars and thirty-six dollars per month, and future promotion is open to those of ability.

Specialized service of this character offers unusual opportunities for the man who is adequately trained. The character of the work will be highly interesting and varied. The man who has the necessary training and ability cannot serve his country better than by joining such an organization.

The foregoing summarizes the general activities of this new regiment. Information may be obtained directly to the Commanding Officer, 56th U. S. Engineers, Washington Barracks, D. C. The applicant must give the following information: (1) age; (2) address; (3) (4) married or single; (5) nationality; (6) will you enlist for the period of the war; (7) brief statement of education; (8) present occupation; (9) experience; (10) name and address of present or former employer.

SCIENCE IN MODERN WARFARE.

(Continued from page 21.)

miles away. By means of sound ranging and wireless telephony, the gun battery on the mainland, the sound was heard clearly and the four shots demolished an enemy battery. Photographs taken after the fourth shot proved it was destroyed.

This is only one example of what goes on every day at the front. Just think for a minute what such a feat means. First, an exact knowledge of the location must be known by means of maps. The preparation of these maps is a stupendous task in itself, involving triangulation from various points and measurements from airplanes and balloons. Next, the characteristics of the enemies' cannon must be obtained and their exact positions in relation to their own battery. After each shot the huge cannon must be put back into position. This is done by finely adjusted optical instruments. Then cannon fire must be made, due to differences in the weight of the shells, the weight, age and quality of the charge of powder, and the age, temperature, and state of the air all produce disturbances, which must be taken into account and corrected. All this entails an exact knowledge of many of the sciences. In addition to these the shell must explode at the proper instant and must have a proper "fragmentation." All this means exact application of science.

Acoustics are also used in mining operations, in locating airplanes at night, and in submarine detection.

Photography has also been carried to a very advanced stage. Nearly all successful offensive operations are dependent on correct maps and ranges, and the taking and correct interpretation of aerial photographs has become a military necessity. The French Army have many schools where the training of observers is taught. A well trained observer can read the art of taking photos and making maps from them.

Electricity, of course, has had many applications in warfare, the most important of which is wireless. Tens of thousands of portable outfits have been made to supply the armies. The secrecy which has been due to the prevention of interference and sorting out of the messages from among the great mass of signals, for during a battle it is a common occurrence for more than fifteen hundred separate stations to send messages simultaneously.

In chemistry, the application has been in asphyxiating gases and tear-producing gases, and, of course, in the making of gunpowder. In France alone there are over twenty city and different laboratories engaged in research work on nitrogen fixation.

VOL. 6, NO. 1.

TELEVISION AND THE TELEPHOT.

(Continued from page 13)

The disposition of this black plate and the telephone receiver is shown in a separate detail sketch, $T$ being the receiver, $D$ the diafram, $E$ the plate. At $A$, we have a source of light, as for instance an electric lamp. The light falls on a planar grid or parallel rays of light which are somewhat modified by the transparent plate in front of $E$. The disposition of the light rays is such that ordinarily the plate $E$ cuts off all the light from $A$, but as soon as the telephone diafram vibrates the plate $E$, more or less light is made to pass thru the latter, which light in turn is sent through revolving plate $G$, the latter has the same helical perforations as the disc $B$ at the sending station. Therefore, therefore, the picture in motion should be formed in the camera at the receiving end, and this picture should correspond with the one sent out from the sender. This picture would then be thrown on the screen of the receiving station as shown. It goes without saying that the two revolving discs must work in synchrony. It is also necessary that the discs be revolved once in one-tenth of a second, which is just the average time of the persistence of the luminous images on the retina of the human eye, and which is supposed to build up the transmitter picture, and in turn is observed on the screen. The length of the receiving end is used merely to enlarge the picture.

(To be continued.)

A NEW PHONOGRAPHIC “LOUD TALKER” FOR PUBLIC PLACES.

(Continued from page 15)

phone attached to the “Cortlandt Street” reproducer, hence thru the lamp ballast, which is usual with the 110-volt loud-speak- ing telephone equipment now used extensively, and so on around thru the one or more multiple circuits of the loud-talking reproducers, which are fitted with horns as illustrated.

We can easily picture just how this arrangement would work out. Let us imagine for a moment that we are passing thru the under-river tube toward New York, after leaving the Pennsylvania Railroad Station in Jersey City. It would be optional, of course, as to whether the guard pushed the “Cortlandt Street” loud-talker push button, and announced the next stop as “CORTLANDT STREET—NEW YORK—ALL OUT” directly after leaving the Pennsylvania Railroad Station stop, or whether she would depress this push button shortly before arriving at the “Cortlandt Street” stop. This, of course, would be a matter for the traffic engineers of the railroad system adopting the device to work out to their own satisfaction.

The action of the apparatus is very simple, and it will be noted by referring to the diagram herewith that when the phono- graph reproducer has reached the end of its record that it would be automatically turned by hand to its original position in the same manner as the penny-in-the-slot automatic phonographs we are accustomed to in public amusement places. Also, when the microphone and reproducer unit have been returned to the starting position, the same mechanism would cause a trigger switch which contact to close a magnetic cut-off circuit, which would trip the magnetic switch when its moving core and attached contacts would at once return to their original position by gravity.

SEND NO MONEY

USE THESE ELECTRICAL BOOKS SEVEN DAYS AT OUR EXPENSE

By merely filling in and mailing the coupon below you can get this complete set of the Cyclopaedia of Applied Electricity on trial. Pay only small shipping charges when they arrive. Use these books for seven full days and then return them for seven days without cost. If you do not want them, you may send them back to our expense and you won’t be out a penny.

A MASSIVE ELECTRICAL LIBRARY—NOT HANDBOOKS

These seven splendid volumes contain all the knowledge you need in order to earn big money in the electrical field. They are not thin handbooks, but thick, encyclopedia-size volumes, handsomely bound in half morocco leather, gold stamped. Each one measures 7 by 10 inches, and is 2 inches thick. This big size permits the use of large and comprehensive illustrations, plates, diagrams, etc. Over 3,000 cuts are contained in the Cyclopaedia’s 3,500 pages.

The completeness of the Cyclopaedia will be a revelation to you. Everything electrical is explained in plain, simple English, every technical point is made clear. Each volume is carefully cross-indexed for instant reference.

50c a Week

For this sum—an insignificant amount of money—every week you get this wealth of electrical information is yours. But you don’t have to send us a penny until you have used the books for seven days. Then, if you decide to keep them, send only $2.00 a month—50c a week—until the special advertising price of $19.80 has been paid. The regular price of these pay-raising books is $35.00.

Consulting Service Free

A year’s Consulting Membership in the American Technical Society—regular price $12.00—will be included with all orders for a limited time. The advice of an entire corps of electrical experts is yours to help you in your progress—free of charge for a year.

Send No Money—Just the Coupon

See these books for yourself before you buy. Remember, you don’t risk a penny or assume a single obligation. The books will be sent to you on approval. If you don’t wish to buy, you will send them back free of charge.

American Technical Society Dept. E-7445 Chicago, U.S.A.

Please send me the Cyclopaedia of Applied Electricity for seven days’ examination. I will pay the shipping charges. If I decide to buy, I will send you $2.00 in seven days, and the balance at the rate of $2.00 a month, until $19.80 has been paid. Then you will send me a receipt showing that the set of books and the $12.00 consulting membership are mine and fully paid for. If I think that I can get along without the books, I will return them after seven days, at your expense.

ELECTRICAL EXPERIMENTER

May, 1918

Regarding the arrangement of the loud-talking reproducers, these could very well be placed along the ceiling of the car or they could be placed on the side of the car, spaced alternately on both sides, so as to give the best distribution of the sound waves. So far as the equipment itself is concerned, the phonograph attachment and its auxiliary mechanisms, including the electric driving motor of small size, magnetic switches, etc., could all be placed in a small cabinet which would readily fit under one of the seats. A two-wire cable only is required to connect the phonograph mechanism with the loud-talking reproducers. To some it might seem that all of the individual records might be combined into "stops," so that we may not have to be tortured many more years with frog-throated announcements of our subway and "L" train guards, which generally sound like a cross between a French artillery barrage and an advance of one of General Byng's tank squadrons.

The phonographic loud-talker would find a wide application in theaters and other public places, and in theaters it would for one thing seem very advisable for the purpose of giving "fire exit" warnings before the start of a show, and also for making announcements of future plays between acts, etc. The loud-speaking telephone itself has been successfully used in push-

Details of Suggested Phonographic "Loud-Talking" Telephone Fitted with Individual Voice Records for Each Stop—in this Instance for the Four Stops Made by Hudson Tube Trains in Running From New York City to Hoboken, N. J. The Loud-Talking Telephone is Now a Common Need but to be Applied to Our Daily Wants.

LEARN DRAFTSMANSHIP

COUPON

FRANKLIN INSTITUTE (The pathway to plenty),
Dept. O102, Rochester, N.Y.

This coupon, filled out as directed, entitles the sender to (1) two specimen examinations, (2) a free copy of our enlightening book, Government Positions and How to Get Them. (3) a list of positions now open, and (4) to consideration for Free Coaching for the examination here checked.
Mail Clerk: ($1,000 to $1,600) Customs Positions. ($1,600 to $1,900)
Postal Clerk: ($1,600 to $2,000) Stenographer. ($1,100 to $1100)
Packet Station Clerk. ($1,500 to $2,000)
Rail Mail Carrier. ($1,100 to $1,600)

Use this before you lose it. Write plainly.

"I Got the Job!"

I'm to be Manager of my Department starting Monday. The boss said he had been watching all the men. When he found I had been studying at home with the International Correspondence Schools he knew I had the right stuff in me—that I was bound to make good. Now we can move over to that house on Oakland Avenue and you can have a maid and take things easy. I tell you, Nell, taking that course with the I. C. S. was the best thing I ever did.

Spare-time study with the I. C. S. is winning promotions for thousands of men and bringing happiness to thousands of homes all over the world. In offices, shops, stores, mines, mills and on railroads, I. C. S. trained men are stepping up to big jobs, over the heads of older men, past those whose only qualification is long service.

There is a job ahead of you that some man is going to be picked for. The boss can't take chances.
When he selects the one to hold it he is going to choose a trained man with sound, practical knowledge of the work. Get busy right now and put yourself in line for that promotion. You can do it in spare time in your own home through the International Correspondence Schools, just as nearly two million men have done in the last twenty-five years, just as more than 100,000 men are doing today.

The first step these men took was to mark and mail this coupon. Make your start the same way—and make it right now.

INTERNATIONAL CORRESPONDENCE SCHOOLS
Box 6361, SCRANTON, PA.

Explain, without obliging me, how I can qualify for the position, or in the subject where I wish to study.

**Violet Rays For Home Use**

Wonderful **HEALTH and BEAUTY GIVER**

Electrify from your light socket transformed into the greatest health-giving agency known to Science—VIOLET RAY—powerfully effective, yet soothing and gentle in action. Benefits of tremendous voltage of electricity absorbed by the human body without the slightest shock muscular contraction or pain of any kind; pleasant and perfectly safe.

**RenuLife Violet Ray High Frequency Generator**

Used and endorsed by physicians and beauty specialists; saturates the body with soothing, invigorating violet rays, producing New Life, Power and Beauty; purifies the blood stream and brings the circulation to parts treated, removes bluish tinge, removes blemishes, pimples, warts, etc.

Every home should have this marvelous invention; benefits every person in sickness or health; smallest infant, invalid, or invalid. It is not a cure-all—but treats successfully a wide range ailments because it is effectual in effect—relieves the symptoms while steadily removing the cause; bringing back normal conditions.

**Treat Successfully**

- **Rheumatism**
- **Neuritis**
- **Lumbago**

**EXPERIMENTAL CHEMISTRY.**

(Continued from page 42)

by heating ammonium nitrate, and when the gas is escaping and free from air (a condition essential to success), pass it up into the other bottle of nitrogen dioxide. It will be noticed that there is no action, barring a slight red fume due to a very little oxygen, with the nitrogen monoxide, whereas oxygen combines with nitric oxide, forming nitrogen tetroxide, which is at once dissolved in the water. Carefully study this distinction.

**Nitrogen Dioxide.**

Preparation:

1. $3 NO + NO_2 = 2NO_2$. The mixture is commonly prepared by the action of nitric acid on copper. One of many other metals act similarly. The acid should be diluted.

2. By the action of a ferrous salt upon nitric acid or a nitrat in the presence of sulfuric or hydrochloric acid.

3. $3Cu(NO_3)_2 + 2KN_3O = 3Cu(NO_3)_2 + 4H_2O + NO_2$

$6FeNO_3 + 2KNO_3 + 4H_2O = 3Cu(NO_3)_2 + 4H_2O + NO_2$

The proportions for the above reaction are 30 grams of potassium nitrate, 250 grams of ferrous sulfate, and 200 cc. of a mixture of one volume concentrated sulfuric acid and three volumes of wa. The colorless gas escapes, which, however, forms brown vapours as it comes in contact with the air; but as soon as the air has been driven from the apparatus it passes off colourless and may be then collected over water.

3. By adding sulfuric acid slowly to a mixture of a saturated solution of sodium nitrate and copper turnings.

$8NaNO_3 + 4H_2SO_4 + 3O_2 = 4Na_2SO_4 + 3Cu(NO_3)_2 + 4H_2O + NO_2$

Properties: (Physical) Nitrogen dioxide is a colorless gas. It dissolves readily in solutions of ferrous salts, forming a black-colored solution, from which it is expelled upon heating. It is upon the formation of this coloration that the test for nitric acid or nitrates is based.

(Chemical) Nitrogen dioxide only sustains the combustion of such substances whose heat liberated is sufficiently high to to cause it to break down into nitrogen and oxygen. Carbon bisulfid (a highly inflammable liquid) and phosphorus burn brilliantly in the gas, the former forming carbon dioxide and sulfur dioxide.

**EXPERIMENT NO. 126. Nitrogen Dioxide from Copper and Sulfuric Acid.**

Have a 250 cc. Erlenmeyer flask of thick glass and corrugated side neck, and a one-hole rubber stopper carrying a throttle tube; or, use a wide-mouth bottle, with a rubber stopper having two holes, one for the delivery tube, (if the flask with side-neck is used, the delivery tube is connected to this side-neck). Put into the generator 10 grams of copper scraps, and add 20 cc. of water, or enough to cover it. Prepare the tray or trough with inverted receivers (8 ounce bottles) filled with water as described in the lesson on Oxygen. After adjustment pour in 20 cc. of nitric acid. A little of the gas should first be rejected, as it is largely mixed with air. If presently the action is not vigorous, add more acid. Notice and observe carefully all phenomena.

After collecting four receivers of the gas to be tested in the following experiment, fill the generator with water, rinse the receivers several times, and then put it back into a receptacle.

**EXPERIMENT NO. 127. Tests and Properties. The Oxygen Test.**

Let one of the receivers get the full test of the gas; and test it by placing the receiver in the trough and holding it upright, noting color, odor, diffusibility. Do you recall having seen this product before? -

**EXPERIMENT NO. 128. COMBUSTION TEST.**

Remove one of the receivers with a glass plate, keeping it covered except as tested.
Thrust into it a burning splint, and notice results. Try it several times to make sure. Try another jar of the gas with burning phlogiston, observe the size of a split pea, first having it vigorously or the experiment will not succeed. Remember, gas is gas, whether phlogiston or combustion. On taking out the combustion cup keep the jar covered in order to examine the fumes.

If the phosphorous burned, observe the color of the flame and the product. How many sorts of fumes can you distinguish? From these tests do you conclude the Nitrogen of Oxygen or a non-supporter of combustion? Do you conclude it is combustible or non-combustible? Is it an oxidizer or a reducer? How would you distinguish all other gases?

Leave one bottle of the gas standing on the shelf (if the trough is used), then prepare an oxygen generator (the test tube with potassium chlorate and manganese dioxide will suffice. (See lesson on Oxygen) and pass some of the oxygen up into the bottle filled with Nitroglycerin. No result and continue the process for some time.

Explain and why you do not obtain the familiar red fumes. What property of the gas is shown by this experiment?

Finally take out the bottle with the water in it and then test it for nitrogen. What does this test show? Is it likely or not that the oxide has combinded with the water? If so, try and determine by employing equations what has formed.

**NITROGEN TRIOXID**

**PREPARATION:**

This gas, known only at low temperature, is formed thru the union of nitrogen dioxide (4 vols.) with oxygen (1 vol.) at -18 degs. 4 NO+O2=2NO2. When a gas is heated with starch, orange-red fumes are evolved which consist of a mixture of nitrogeon trioxide and teteroxide. On passing these vapors into a vessel containing starch, a fine white fume forms. The fine fume is a liquid. Pure tetoxide at -10 degs. is an indigo-blue liquid. Above 12 degs. the liquid begins to decompose; TN2O5+H2O=2NO2+HNO3. With a small quantity of water nitrogen trioxide forms nitrous acid; NO+H2O=HNO2+NO. With a large quantity of water decomposition takes place and nitric acid results: 3N2O5+H2O=2HNO3+2NO2

Nitrogen trioxide and nitrogen peroxide are red-brown gases, which can be distinguished from each other except by volumetric analysis, their chemical characters being nearly identical.

**FIRE AND BUMS**

**INTENSELY POISONOUS AND STRONG AGENTS.**

**NITROGEN TETROXID OR PEROXID.**

**PREPARATION:**

Nitrogen tetridox is prepared by:

1. Thru the union of nitrogen dioxide and oxygen. NO+O2=NO2
2. Heating lead nitrat: Pb(NO3)2=2PbO+NO2+2NO

The gas may be liquefied by passing into a vessel immersed in ice and salt.

**PROPERTIES:**

Nitrogen Tetroxid is a dark gas which is readily cooled to a light yellow fluid. With a little cold water, nitrogen tetridox forms nitrogen dioxide and nitric acid, with an excess, as also aqueous solutions of alkalis, nitric, and sodium nitric or their salts and acids.

NO+O2+H2O=NO2+HNO3

**EXPERIMENT NO. 109.**

**NITROGEN TETROXID FROM NITRATES.**

Put into a small test tube four or five drops of water nitric acid. Hold the tube in the hand with a tube holder and point it toward the right, keeping the lower part of the tube in the hot part of the Bunsen burner, and, having a glowing splint in the right hand, thrust it into the tube near the axis of the action begins. This test is merely to show that oxygen is also liberated, together with the oxides. Be careful not to repeat several times.

Notice the sound when the crystals are heated. Note the color of the fumes and their odor.

Not all nitrates break up by the application of heat; for instance, sodium or potassium nitrit will not, and ammonium nitrit will give a different result, as you have already observed.

**EXPERIMENT NO. 130. FROM NITRIC ACID.**

Most metals heated with nitric acid give NO, either directly or indirectly by the union of oxygen of the air with the dioxid or directly. Test the action of the acid on tin-foil in small pieces, heating it if necessary.

3Sn4+HNO3+H2O=3SnO2+4NO

What kind of a substance is it? It is called *Nitric Acid.*

**EXPERIMENT NO. 131.**

Put about a gram of fine charcoal in a test tube, heat it till it glows, then let fall two or three drops of acid free water into another tube. Note any phenomena. Heated starch or other carbonaceous substance acts in a similar manner. When nitric or a nitrous acid is the immediate reduction product is NO, but in case any present either from the air or from the product itself the balance of the two is so great that combination at once occurs. Occasionally the secondary action of reduction does not give NO or NO2, but free nitrogen or even ammonia. (NH)3

**EXPERIMENT NO. 132. NITROGEN TETROXID, COMPOSITION.**

From Nitrogen and Oxygen. Invert a 50 cc. cylinder, gradually filled with water in a trough and clamp it in position so as to collect 40 cc. of gas in it.

With a nitrogen dioxid generator (using Cu and HNO3) collect the gradient in 40 cc. of the dioxid, take care to expel all gas from the generator before allowing any gas to collect, and noting exactly the volume of NO.

Arrange in another trough a second gradient which may, if desired, be smaller than the first, and close and clamp so as to collect 20 cc. of gas. Prepare an oxygen generator (employing potassium chlorate and manganese dioxide), and when all the air has been driven out of the second isotherm fully, collect 20 cc. of oxygen in the last graduate, that is, half as much as NO. Set aside both generators.

Now transfer the gas containing the dioxid to the other trough and clamp it in position. This is done by sliding the mouth of the gas into the tubing of the gas half filled with water. No air must be admitted. The reason for the transfer is that when NO is generated about 10 per cent will dissolve in water trough, and it absorbs much oxygen as the latter is poured upward.

Next unclamp the oxygen graduate and carefully pour the contents in successive portions up into the graduate containing NO. An inverted funnel may be used if necessary.

If the experiment is made with sufficient accuracy, the graduate should be completely filled with water at the end. If it was not in your case, can you see any reason?

**Record the Results:**

Volume of NO collected (v).

Volume of 0 introduced (v).

Ratio of NO to O.

Symbol of Nitrogen Tetroxid.

(To be continued.)

RADIUM IN JAPAN.

A careful investigation of Japan's mineral and hot springs proves her to be the richest country in the world in radium-bearing waters.

The U. S. Government, ever on the alert for any aid to efficiency, is giving the electric potato peeler a thorough test. This should make things a little easier for our "Sammies" and give them more time for "Bagging Boches."

FIXATION OF NITROGEN BY ELECTRICITY.

(Continued from page 2)

there is no longer danger of its dissocia-
tion, it has then reached so to say a false
harbor. In order to do this rapid cooling it
is necessary that the air be past very
rapidly thru and out of the high tempera-
ture of the electric arc, or better still that
the electric arc be past very rapidly thru the
air. This latter principle is carried out in
the famous Birkeland-Eyde process which is
used at present on a large scale in Norway,
Germany and other European countries.
The Birkeland-Eyde system is illustrated
in figure 1.

Two large electro-magnets A and B are
placed on both sides of a powerful electric
arc C. When these electro-magnets are
energized we have practically the same dis-
position as in the well-known magnetic
blow-outs, that is to say, that the arc C
will be moved or blown away by the mag-
netic field which crosses it at right angles.
As this arc is being blown out entirely, there
should be provided some means by which it
can be re-established every time that it is
blown out. In the Birkeland-Eyde process
this is done by using an electric pressure
of 5,500 volts across the electrodes. This
high pressure jumps the gap D every time
that the current ceases. This spark immedi-
ately starts a new arc, and in this way a rapid succession or train of electric arcs is ob-
ained. In reality the electrodes between which the arcs take place are hollow and water cooled and they are represented as shown in figure 2.

As alternating currents are used in this
system, the arcs are blown alternately in
the direction E, and then again in the di-
rection F. The result is a series of huge
electric flames of semi-circular shape as
represented by the dotted lines, growing
rapidly from the center and moving at a
tremendous speed away from the center.
The air thru which these arcs are being
drawn becomes very rich in nitric oxide,
and the continuous supply of air which it
is cooled off is mixed with more air
so that the nitric oxide gas which it contains
oxidizes still higher and then it is past thru water with which it combines to nit-
ic acid. It is claimed that about two per-
cent of the air which has been treated in
this way is gained in the shape of nitric
acid. As this claimed of course finds itself is rather low, the electric power used
in this process must be cheap in order to
make it go. It is for this reason the plants
for this electric fixation of nitrogen out-
of the air are almost invariably lo-
cated in the mountains where cheap water
power can be directly turned to the
required electric power. The plants using
this system claim to produce 600 kilograms
of nitric acid per kilowatt per year. A
remarkable feature of this electric system
is that it requires nothing in the way of
materials but water and air.

The process of fixation of nitrogen by means of electricity is illus-
trated in figure 3.

A long electric arc of twenty feet is main-
tained between an electrode A and the
inside wall of a long iron tube B. By
means of a water-jacket C, the upper part
of the iron tube is kept cool, so that the
electric arc, which has a natural tendency to

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.

RADIO AND TELEGRAPHY.

According to the latest information, the	

NATIONAL TELEGRAPH COMPANY

14 BROAD ST., NEW YORK.

May 1, 1918
climb up against the inside wall of the tube, can not extend farther than the line M—N. Air is forced thru this iron tube from the bottom upwards. This air passes thru the electric arc and thus the nitric oxide is formed. When this air reaches the line M—N where the cooled part of the iron tube begins, it is immediately cooled off and consequently secured against dissociation. The obtained nitric acid gas is then first oxidized to a higher degree by intermediate heating and finally treated with water so that nitric acid is obtained. In this Shöntherr process an electric pressure of 5,000 volts maintains the long electric arc. Alternating currents are used here also.

By means of side openings, the air which is blown thru the tube is given a gyratory motion, which results in the electric arc being maintained exactly along the centerline of the tube.

The Pauling process is illustrated in figure 4.

Here an alternating current of 4,000 volts pressure maintains an electric arc between two hollow ornately surmounted by a wire as represented in figure 4. This arc, when established, is driven upwards by a blast of air and is disrupted by the diverging horns. The arc will spark over at A and so on. The effect is to create an arc flame about thirty inches high and to have this flame impinging upon the moving air used to blast the arc flame. Here also the obtained nitric oxide gas is first oxidized to a higher oxide and then past thru water so that nitric acid is obtained.

The Pauling and the Shöntherr processes compete favorably with the more famous Birckeland-Eyde process. All three processes exist on a large scale in many European countries, but have hardly found their way as yet in America.

THE PHENOMENA OF ELECTRIC CONDUCTION IN GASES.

(Continued from page 25)

As ions can neither be seen or separated in order to measure their individual velocities, which no doubt vary, we have them directly as we can, let us say a race horse or a cannon ball. The method of Winkler and Weichert was first developed and is very ingenious one. He constructed a tube in which the cathode rays were made to vibrate back and forth across a screen which was the anode. He then used a mirror which was behind which another screen was located. The swinging of the rays was controlled by an oscillating field of high frequency, a period of which could be calculated. The arrangement was so timed that the rays past the first screen at the end of their swing to one side, and reached the other screen in the middle of their swing back again, so that the time taken for the rays to pass from one screen to the other was just an integral period of the oscillating field. The number of oscillations of the field was determined by small conden- sers whose capacity was known; hence it only remained to calculate the time for a quarter vibration, and reduce the distance for that time to centimeters per second. The data are accurate and constant, and the honor of making the classic determination of the velocity of such ions must be awarded to J. J. Thomson. All other indirect methods are very simple and for this reason also quite accurate. His method was to pass the current, as in Fig. 4, allowing the ions from the cathode C to pass thru a small perforation in the anode A, to a luminous screen at the opposite end of the tube. At the point EE and MM, however,
two electrodes EE, and the poles of an electromagnet MM, were situated at right angles to each other so that the rays could be deflected in opposite directions by either a magnetic or electric field. The procedure was then to first deflect the rays by an electric field of known strength to any point B on the luminous screen; then to increase the magnetic field in the opposite direction until the rays were just brought back to their original position again.

By knowing the strengths of both the magnetic and electric fields it is easy to calculate the velocity of the rays, for it is a well-known fact that the force of an electric field on an ion does not depend on the velocity of the ion, while the force of a magnetic field on an ion does depend on the velocity of the ion, or in other words upon the number of lines of force it cuts per second. These facts may be expressed by simple formulas well known to students of physics, as follows:

$$H ev = V e$$

or

$$V = \frac{H e}{v}$$

where

H and V are the strengths of the electric and magnetic fields respectively, "e" is the charge on the ion and "v" is the velocity of the ion. In the experiment the rays were brought back to zero so that it is evident both fields are equal, therefore:

$$V = \frac{H e}{v}$$

mined from V and H which are known, or can be measured.

From such determinations it has been found that the positive ions in a tube like the one shown may travel as slow as 600 miles per second, and from their size they are identified as helium atoms. Others traveling at approximately 2,000 miles per second appear to be hydrogen atoms, which are the smallest positive ions so far known. The negative ions travel in such a tube at about 100,000 miles per second or even as high as the velocity of light, and are without doubt free electrons. Under other conditions much slower moving ions are found than any mentioned and they probably correspond to the groups or clusters mentioned earlier. Much work is now being done to determine the nature of ions under different conditions, and this bears directly on the problem of the nature of Electricity itself.

EXTERNAL GRID VACUUM VALVE DETECTOR CONSTRUCTION.

(Continued from page 28)

A glimpse of a semi-finished detector is presented in Fig. 3, in which the outside grid has been lowered to give a clear view of the interior of the bulb. In this picture the base wires are shown separate not connected to the necessary leads which are shown elsewhere.

Some idea of the finished appearance of our detector may be gained from a survey of Fig. 4. The grid on these valves is made of perforated aluminum or nickle laden brass. The holes can be punched by hand or the material bought in the finished state.

It may be that some who glance at this article will form the opinion that the detectors illustrated will not give good results on account of the small area and positions of the internal parts. This, however, has not proved the case, as the author’s experiments with the bulb actually pictured here have proved them quite sensitive under the right conditions.

The matter of current regulation with this valve is a rather important one. In
order to operate the valve efficiently the filament must burn brightly and should be fed at about 20% above the specified voltage, the exact amount varying with changing conditions. For low voltage radio work the filament may be as high as 80%, but for high voltage radio work the filament should be as low as 60% to provide a margin for any condition of service.

A telephone circuit battery of about 60 volts is generally considered quite sufficient for the majority of telephone or radio-day valve operations.

In the case of the bulbs under consideration it is best to command a high voltage potential, of the order of 50 volts, although very good results can be obtained with as little as 50 volts. The current from the cells which form this battery must be controlled by a potentiometer of very high resistance, or best type, so that no radiating circuits may be substituted therefor. The author has found during his tests that a potential of 50 volts, subjected to the regulating effect encountered by using the skin of the hand or fingers as a rheostat, gave unusually good results.

The heat of using one or both of these types of body as a current regulator is, of course, impractical, but the resultant effect is so striking that it leads the author to believe that a new instrument, if developed, may take the place of the present potentiometer, which is known to be a very wasteful instrument. An adjustable bank of receivers of different resistance, such as a single pitch, connected with a common sound chamber or horn, should entirely eliminate the need of a potentiometer and it is also a characteristic of employing a variable condenser in this connection to approximate the capacity effect obtained in using the body as a resistance.

During the war it will naturally be impossible to test out any form of wireless instruments, except in the laboratory, where better type, so non-radiating circuits may be utilized, and even then there be a number of possible conditions set where the limit of sending power available now. No aerial or ground lines are permitted under the recent Radio Act.

For the real electrical experimenter and radio enthusiast it will remain a matter of considerable interest that in this field in which to work with any type of valve-amplifier that is not too highly valued to experiment with. Two of the many possible combinations of electronic circuitry may be put outside the radio field are considered separately in the following paragraphs.

Hot filament valves are slowly coming into use as rectifiers of electric current in commercial stations, but are still considered in the chrysals, or unfinished state. The great drawback in using bulbs for this purpose lies in the excessive waste of filament which takes place, making the rectifier very short lived. It would be folly to use any serious experiment for experimentation along this line, but one of our lamps, which cost only about 60c to replace, may be used without any one's being considered a pinch hitter again. By using the filaments interchangeably at intervals of a few hours each it may be possible, under the right conditions, to get a life of 500 or 600 hours from some of these bulbs when used as model rectifiers.

The most wonderful property of the vacuum valve, and the one which makes it the ideal instrument is doubtless its ability to act as an amplifier. For increasing, indirectly, electrical energy and making the electric current presents a very desirable medium. Many systems of automatic sound control are being developed with the aid of the amplifier valve. There is no limit to the possi-

bilities of experimentation in this direction. Loud-speaking megaphones, phonographs, telephones, horns, ad infinitum, all await development. Submarine destroying devices and various types of apparatus of all kinds, can be invented which will prove to be the undoing of things out of sight, but not out of the hearing of the enemy, and whose operation is augmented and sensitized by the addition of an amplifier bulb.

It is the author's hope that the foregoing ideas may prove of real interest to a very large class of readers.
Submarines, torpedoes, flying machines, machine guns, immense howitzers, the British "tanks," and an untold number of other products of American brains, are dominant factors in the Great War. We are just starting, our "YES"—ingenuity must be "YES"—Uncle Sam—the whole civilized World—is seeking ideas that will aid in the fight. Can't you help with even ONE of thousands of simple things that will win recognition—perhaps fortune for you?

The need is for inventions of peace, too. Never before was there such a demand for new ideas of all kinds—never before have so many inventors and other patent owners, written me for good things protected by OWEN PATENTS. There is, to-day, a manufacturer wanting YOURS. Write for my free booklet and see—read for yourself the hundreds of requests recently received.

You incur no obligation by writing me. My advice costs nothing and I make no charge for an opinion as to patentability of your idea. If my opinion is favorable I will back it up by a Guarantee Contract which protects you fully. If you want to sell your invention, I will help you, and will advertise it, free of charge, in "INVENTION AND MANUFACTURING.

A simple request will bring you to us, at once, my four free booklets—"SUCCESSFUL PATENTS," a 72 page guide telling how to proceed, gives references, etc.; "STIRRING STORIES," tells the true story about inventions, gives hundreds of hints of inventions wanted, etc.; "PATENT BRITISH" published of many discovered by others who want OWN PATENTS, together with ideas they want; "PATENT PROMOTION," tells you how to sell, why some inventors fail, discusses the value of your idea, etc.

Write for these books to-day, I will send you a signed agreement that will protect you before you disclose your invention.

RICHARD B. OWEN-Patent Lawyer

PATENT YOUR IDEAS
—is there an invention tucked away in your brain?

If so, now is the time to produce it. Manufacturers everywhere are demanding new articles to keep up big production. Their wants must be supplied.

This is your opportunity!

Many manufacturers have written us saying just what they are looking for; we will send you this List of Inventions Wanted, Free for the Asking.

Hundreds of other manufacturers have written us for anything new and useful—kitchen utensils, household articles, automobile specialties, labor-saving devices for the office or farm—anything from big machinery to small novelties—anything to save time, make or do its work better. Thousands of new plants have been built and others have been enlarged. Many are making articles for which there is only temporary sale. All want something which they can build to sell as a steady, permanent business. Wise manufacturers are laying their plans now. This is why they are scouring the country for NEW INVENTIONS. IF YOU HAVE AN INVENTION send us a sketch or model and description and we will give you a FREE OPINION OF ITS PATENTABILITY. We help our clients sell their patents. Patents applied for through us are advertised for sale free of charge in the Manufacturers' Record. If you have no idea at present, write us for our list of articles called for by manufacturers.

We will also send you our book "WHAT TO INVENT" giving information which everyone should have.

Both the list of inventions wanted and the book are free
CHANDLER & CHANDLER, 415 7th St., Washington, D. C. Patent Attorneys

A Handy Helper for the Shop and Workbench
This "Red Devil" mechanic's plier is recommended for all kinds of practical and experimental work.

"Red Devil" No. 50
Forged from tool steel, spring tempered. Tested cutting edges, "scientific" handles.

From dealers, or if not, from us. Send $1.30 for a sample 7-tn. tool, style No. 58. Write for Tool Literature.

SMITH & HEMENWAY CO., Inc., 107 Coot St., Irvington, N. J.

You benefit by mentioning the "Electrical Experiment" when writing to advertisers.
A. This is a very clever idea, and quite novel as far as we can see. We have never seen the like of it, and would advise our correspondent to get in touch with a patent attorney.

**ENVELOPE.**

(221) Leo M. La Fave, Black River, N. Y., has submitted to us a simple combination envelope and letter, the idea being to fold the letter in such a way as to make an envelope out of it. This letter has, of course, a special flap, so that the combination can be sealed. Our correspondent wishes to know if this device is new and patentable.

A. This is not a new device by any means. Quite a good many envelopes of this kind are on the market now, and we know of a number of concerns who are using such envelopes at the present time.

**GUN KICK-ABSORBER.**

(222) Erwin L. Gehrke, Cleveland, O., submits a device to be attached to a gun whereby the kick of the gun is absorbed. It is a well-known fact that a soldier firing a gun for a long stretch of time is apt to develop soreness in the shoulder by virtue of the powerful kicking back of the gun. By means of certain spring arrangements, our correspondent intends to do away with this feature.

A. This is by no means a new idea, kick absorbers of this kind exist at the present time and have existed as far back as one hundred years. Somewhat or other the idea does not seem to be very popular with the various governments, particularly nowadays, as a good deal of progress has been made in gun building, and the modern rifle does not give the heavy kick that such guns used to give, as, for instance, the old style musket.

Our correspondent, furthermore, writes as follows: "An idea has come to me concerning a method to heat the water in a boiler. This would be chiefly used in the recently invented "Doble Car."

He goes on and describes a system whereby a generator of the correct power is geared to the steam engine, storage battery to be charged by the generator while the car is running, and to be automatically disconnected when charged. The purpose of the storage battery would be to take the place of the generator while the car is at a standstill, in order to keep the correct amount of steam up continually. The heating of the boiler in this case will, of course, be electrical, and our correspondent describes his method minutely.

A. This is a very good idea, but we are not quite certain that it is of any practical value without having it tried out. In a way, the idea is quite new, and there should not be much trouble in patenting it, but we would advise caution, and at least preliminary try-out.
ELECTRICAL EXPERIMENTER

May, 1918

$50,000,000
For One Little Idea

The little tin cap with the wrinkled edge that you jerk off of beer bottles and other bottles, that simple little thing has made something like fifty millions of dollars as a patent, according to an eye that has seen many a useful device or gadget in its day, or any number of articles that we all handle in our daily life that have made fortunes for the men and women who say the worth of their inventions or the products of their craftsmanship. There's no quicker, surer, or more legitimate way of attaining wealth than through an invention. Yet how few of us take advantage of the opportunities that we all have for producing an infallibly profitable invention?

What Shall I Invent?

There are two reasons for doing an invention. One way by making some improvement on an existing article or process already in use, the other is to create a new, useful device or gadget, or article of manufacture, or process, and go after the thing to invent, that is entirely up to you. However, you should deem it necessary to think of something stupendous, something that will go into fields beyond your everyday life. Right in your own own home, office or shop, there are countless opportunities for invention if you will but do it. Some of these inventions and patents to guide you, and for this reason it would be well for you to lay hand at such a book as "Patents for Inventors," which can be obtained free by writing George P. Kimmel, the well-known Patent Attorney of Washington, D. C. (85 E. Oriental Building, Washington, D. C.)

Send for Free Booklet

It will well pay you to send for Mr. Kimmel's free booklet. It will teach you much about patents. Write the procedure, and will tell you how important it is to select the right patent attorney to get your patent and to aid you in selling or promoting it. By a patent you can protect your most valuable inventions and the profit you would otherwise lose. This booklet is sent to you free of charge. Write direct to Mr. Kimmel.

PATENTS
THAT PROTECT AND PAY

Books and Advice Free

Send your Ideas. Manufacturers want patents! Inventors invent to protect their inventions. Get yourself a successful patent attorney with highest references. Honest service! Write immediately! "Best Book on Patents Free" to J. R. KELLY, 7640 Woodland Bldg., Washington, D.C.

AUTO GAS TANK

(226) L. B. Wilson, Kalamazoo, Mich., submits an idea for an automobile gas tank which is supposed to keep a reserve supply of gasoline. The arrangement is such that instead of the gas tank being the ordinary gas tank, it is automatically filled when the temperature rises above a certain degree, the fan will start running, thereby cooling the atmosphere. Under the Wilson system, the reply of the manufacturer and the rest of the product will be certain. A tank is connected into the circuit, which in turn throws hot air into the room, thereby heating it. A capital idea; very good and very simple. We are quite sure that our correspondent will find little trouble in securing a patent, which we are certain should prove valuable. He should get in touch with a patent attorney at once.

THEORY OF TUNING, WAVE LENGTHS AND HARMONICS.

(Continued from page 39)

If the frequency of the applied pressure were increased three-fold—that is, to 180 cycles per second—the necessary frequency to be employed with the given condenser to produce resonance would be

\[ L = \frac{1131}{1131} \times \frac{0.1131}{1131} \]

or one-ninth the amount required originally.

If the applied pressure E and the resistance of the coil is the same as before, the current in the circuit will be 11 amperes as before. It is now a simple process to comprehend the application of the foregoing to a wireless set, wireless, or low resistance telephone receivers connected as indicated in figure 4, or with high resistance receivers connected between the terminals of the condensers as indicated in figure 5.

The applied pressure E may be produced by wireless waves being reflected on the aerial. This pressure E may, of course, be of any value depending upon the energy available at the receiving device due to the distant transmitting apparatus. There may be three different wave frequencies from these different sending stations operating through space at the same time, one having twice the cycle frequency of the second and three times the frequency of the first. By slowly moving the contact P along the turn of the spiral a better coil the values of the inductance L is so varied as to produce resonance and a maximum current in the telephone receivers for one of the frequencies. The currents due to other frequencies may produce a certain small current in the receiving circuit, and weak sounds in the receiver. By moving the contact P along the position for one frequency, to another position, a certain position is found such that resonance and a maximum current is produced through the receiving circuit. The maximum current for this frequency produces a much louder note in the telephone receivers than the currents due to the remaining frequencies, which are now said to be "tuned out."

The higher the frequency of the wireless waves producing the pressure and resulting in current in the receiving circuit, the higher the pitch of the note in the receivers.

It may be well to call to mind the relation of frequency and wave length. The higher the frequency, the shorter the wave length, as indicated by the equation \[ V = \frac{E}{\lambda} \]

in which V denotes the frequency of propagation of a wave of a certain wave length, \( \lambda \) (Greek letter lambda) denotes the wave length. The velocity V of propagation is the same for all wave lengths. That is, V is a constant; so if \( f \) is decreased, then \( \lambda \) must be correspondingly increased.

The importance of the numerical value of the resistance R of the receiving circuits considered. Considering the original equation

\[ \frac{1}{2\pi^2f^2R} \]

it may be seen that when \( 2\pi^2f^2R = \sin^2 \theta \)

the current is express by \[ I = \frac{E}{R + \frac{E}{\sin^2 \theta}} \]

which shows that at perfect resonance with a given value of applied pressure, the smaller the numerical value of the resistance of the coil or of the complete circuit, the larger will be the current in the coil or circuit, or in a telephone receiver when connected as in figure 4.

In such an arrangement it is evident that the smaller the resistance of the receivers the greater will be the current in them. However, the sensitivity of a telephone receiver depends very largely upon the
ampere-turns. When arranged as in figure 5, 6, the receiver would naturally have a much greater resistance than when arranged as in figure 4, since when connected across the contacts it is exposed to very high pressures. The greater resistance does not imply, however, that they should be wound with wire having a high resistance. In fact, such is not the case, since large value of ampere-turns is desirable. If copper wire is used in winding the electromagnets of the phones, a given resistance wire can produce more ampere-turns and therefore more ampere-turns, than if wire having a higher specific resistance is employed.

Coi's wound with insulated wire so arranged with a variable contact device as to have their inductance varied at will throw out a considerable range, are called tuning coils when used in connection with wireless receiving apparatus, and it is interesting to note that as the contact P shown in figure 2 is moved so as to reduce the number of turns, that is to decrease the inductance, at the same time the resistance of the circuit has also been decreased. That is, the decrease in resistance and inductance must occur simultaneously in such a device. Reducing the number of turns reduces the actual length of wire in circuit.

The tuning might be effected by drawing an iron core in and out of a coil, which wire, when the core was drawn, would be sluggish in action, and of course would not vary the ohmic resistance connected to the primary. Another method of varying the inductance might be effected by constructing the coil of two portions, arranged to move with reference to each other, and the variations in inductance is said to be effected by mutual induction, and the ohmic resistance of such apparatus is constant.

Harmonics.—Any interesting and instructive aspect of the tuning coil is in tuning a circuit to respond loudly to the various harmonics of any single fundamental wave that is being circuit from the sending station. This may perhaps be best explained by considering the shape and composition of alternating-current waves or curves. It is impossible to define just what is meant by an "alternating-current curve or wave." A true alternating pressure, current, or magnetic field is one which has the same wave shape or respective values in each successive second, and one that is produced in accordance with a definite law: Thus, the alternating current or so-called sine curve, shown in figure 6. Such a curve is constructed by first drawing a circle, as shown at A, and laying off on a horizontal straight line, the length of the circumference of the given circle. The length is shown as OX in the figure. Op is therefore half a circumference, Oq one-fourth of a circumference. The sine curve may be constructed by first erecting at point B a vertical line equal in length to the radius of the circle, and then a vertical line equal to the line A'B, which is called the sine of the angle A'OB. In short, all the verticals erected on the horizontal base line represent the sines of corresponding angles of the center of the given circle. The dotted horizontal lines in figure 7 are the feeder idea as to the construction of the sine curve.

Now every true alternating wave of any shape whatever is made up of a certain number of these simple sine curves added together. The so-designated resultant curve in figure 7, the 1st harmonic curve, which is made up of three simple sine curves all starting at the zero point O, and all increasing in the vertical or positive direction. It may be noted that one of the component sine curves has the same frequency or wave length as the resultant curve. This sine curve may be called the 1st harmonic. Another component sine curve has three times the frequency, hence one-third the wave length of the resultant curve. This sine curve is called the 3rd harmonic. The other component sine curve has five times the frequency and one-fifth the wave length of the resultant curve. The resultant curve is composed of an infinite number algebraically the vertical heights of all three of the component sine curves at each point chosen. The resultant curve indicate those points that were chosen in order to construct the particular curve.

By algebraical addition is meant that at any given point on the horizontal all vertical distances of all sine curves extending below the horizontal must be subtracted from the vertical or the sum of the verticals extending above the horizontal at the same point. At points where all the component curves pass thru the horizontal datum line, there of course the resultant curve also passes thru the horizontal. It is evident that a great variety of resultant curves could be constructed from the three simple sine curves by simply varying the heights or amplitudes of these curves, or of only one of them. Every alternating wave of pressure if applied to any circuit will produce in the circuit an alternating curve of current that is also made up of component sine curves. It may, for example, be supposed that figure 7 denotes an alternating pressure E impressed on a circuit as shown in figure 8; if properly adjusting the movable contact P, resistance may be produced in the circuit with reference to the third or harmonic component of the applied pressure, causing the maximum current in the receiving circuit having a frequency just three times that of the fundamental or resultant pressure and current. The predominating tone in the receiver has a pitch or frequency three times that of the fundamental or resultant curve. By still further decreasing the variable inductance, the fifth harmonic may be made predominant. If an impart pressure is made up of, say, fifteen harmonics, the tone of the coil has sufficient range in adjustment, the fifteenth harmonic might be made the predominant one. As the frequency goes up, the wave length becomes lower. Thus the third harmonic has a frequency three times the fundamental, and a corresponding wave length of one-third that of the fundamental.

Another interesting fact in connection with the matter of "tuning" may be alluded to here, that has a very important relation to music. Nearly every person can distinguish the musical tones given out by a violin from those given out by a cornet or a piano. That is, tone having a definite pitch or frequency given out by a violin has a very different quality from the same tone or note of the same frequency produced by a piano or by a cornet. When all these instruments are tuned to, say, middle C, they each produce a note having the same frequency or the same pitch; that is, the same musical sound sent out by each instrument is very different.

This may be illustrated diagrammatically by figures 7 and 8. The resultant curve in figure 8 is made up of the sum of three sine waves as indicated, but has a very different shape from the resultant curve in figure 7.

The two resultant curves might have exactly the same wave length (distance from O to X), that is the same frequency, yet disturbance of the wave from one to another. Two wireless waves having exactly the same frequency may readily be distinguished by an expert operator simply because of the characteristic of quality. It may be valuable to have devices that will tune not only for pitch but also for quality.
27 YEARS THE ENEMY OF PAIN

ELECTRICAL EXPERIMENTER

THE HOW AND WHY OF RADIO APPARATUS.
(Continued from page 30)

A potentiometer resistance. The sealed-point containing the fine Wollaston wire is made positive. No adjustment is necessary with this detector. If dry cells are used, a switch being provided as shown. The electrolytic detector is extremely sensitive and can be made up in a few minutes in emergency. It does not "jar out."

The Bare-Point Electrolytic Detector has been the subject of much discussion among radio men as to who really was the basic inventor of it. But most writers of the day give credit, jointly, to Dr. Michael J. Pupin (1889), Professor Reginald A. Fessenden (1903) and W. Schloemelich (1903).

The action of this detector is based upon the fact that if an extremely fine platinum wire, measuring a few ten-thousandths of an inch in diameter is allowed to partially immerse its extremity in an acid solution (such as one composed of five parts water and one part nitric acid) that an incoming Hertzian wave current will tend to arrest the strong polarization (the production of fine gas bubbles) set up about the fine platinum wire, which is usually made the anode in the battery circuit. Further, the electrolytic detector has been found by Professor G. W. Pierce to act as a rectifier and that the inherent action is also based on polarization capacity at the electrodes as first described by Pupin in 1899. Dr. L. W. Austin and others have found that the fine platinum wire may be positive or negative for feeble oscillations with equal results. The acid solution is contained in a glass or carbon or zinc cup, and this acts as the cathode in the battery circuit. This detector possesses the function of acting as its own battery when a carbon or zinc cup is used, as this forms a minute carbon (or zinc) acid, platinum. This inherent battery action was intensified considerably by using a special amalgam in the acid solution in a detector of this class developed by H. Gernsback several years ago. The self-excited electrolytic detector has never been found (Pierce) to be as satisfactory as the externally excited one for feeble signals.

The operation of the sealed-point type ("RadioSon") is the same as in the bare-point electrolytic type of detector and a battery of two dry cells is used with it, together with a pair of high resistance telephone receivers and having the battery couple preferably by means of a high resistance potentiometer.

Science, the Wonders of Chemical and Electrical Phenomena

The last news of recent military inventions, all kinds of fine articles on how to construct things of a chemical and electrical nature, hard to get formulas, interesting experiments, curious things from the World of Science, Stamps, Minerals, etc. A Question Box and a Round Table Department make this magazine just chock full of interest from cover to cover. A Complete Course in General Analysis written by the Dean of the United States College of Chemistry, is now running in the Current numbers. You cannot afford to be without this magazine.

SPECIAL LIMITED OFFER

With the appearance of this ad, our offer of six months for 25 cents is closed, but we have something better. Just think of getting a full year subscription to this wonderful Magazine for only 75 cents. No stamps will be accepted. 12 big issues, fully illustrated. Send in your subscription to-day, before this offer is withdrawn.
The advantage of this type of electrolytic detector is that the acid is scaled in, consequently does not spill or evaporate. The tinker is used a great deal in translating undamped signals. It was devised by Poulsen and employs a small vibrator or rotary contact interrupter as shown at Fig. 4. No detector of the ordinary kind is used. The condenser connected across the phones should have about 82 m. capacity. It can be of the paper and tinfoil type.

The Fleming Value Detector of Hertzian oscillations (Fig. 5) is based upon the principle that if we have a hot or incandescent electrode, and also a cold electrode, both of which are connected to an evacuated glass chamber, a rectifying action will be created, i.e., that negative electrical charges, such as those from a battery of 30 to 40 volts or even less, can pass from the hot filament to the cold electrode, but not vice versa. In the Fleming Valve the cold electrode takes the form of a metal cylinder surrounding the incandescent filament. This arrangement acts as an electrical valve for passing or alternating currents of any frequency. The space between the cold cylinder and the hot filament is therefore said to possess unilateral conductivity. The Fleming Valve possesses a fairly high sensitivity; it is used with a pair of high resistance head phones, a suitable battery and auxiliary regulating apparatus. The wire less receiving phenomenon occurring will be evident from the foregoing and is, in a sense, of a rectifying nature similar to that possessed by the mineral detectors.

Since the Fleming valve detector has a very high resistance, the condenser C should be very small, the inductance L relatively large, and the telephone receivers wound to a very high resistance, say 4,000 to 5,000 ohms, recommends Dr. W. H. Eccles. A peculiar fact about this detector is that its action is interfered with if the glass of the bulb becomes statically charged; hence the bulb is surrounded by a copper gauze screen which is earthed by connecting it to the battery supplying the lamp filament.

The Audion Detector (Fig. 6) employs three distinct electrodes as shown, viz., a filament—a grid—and a wire or plate. The grid, composed of a wire member as indicated, is placed between the filament and the wire. The oscillations when they pass thru the Audion detector are subjected to a similar action to that occurring in the Fleming Valve when they are received, but in so doing they are claimed to also effect a relay action with respect to a high voltage battery of 40 to 50 volts potential, connected to a pair of high resistance telephone receivers in the relay circuit. With the Audion it is seen that, owing to the suggested relay action inherent in its operation, it is quite possible and practical to have a relay action occurring of considerable magnitude; that is, the ratio between the amount of energy passing into the Audion from the antenna circuit and the amount of energy controlled by the relay or trigger action in the high voltage telephone circuit may be quite large.

There was, for a number of years, a great controversy on the subject of the enveloping or the Marconi experts as to the validity of the Audion patents. This matter was decided in favor of Marconi in May, 1916, and also in the December, 1916, issues of this journal, and to those interested had read both of these excellent articles as well as a very exhaustive article explaining the electronic action of the Audion which appeared in the August, 1916, issue of The Electrical Experimenter.

The Marconi magnetic detector is a battery-less type much used on shipboard. It is illustrated at Fig. 7. The detector illustrated is equipped with a Marconi Magnetic Detector. This instrument operates on a very unique principle, viz., that of the reduction in any hysteresis effect having such a value as to almost entirely nullify the core effect of the subject to the effect of a Hertzian wave current passing thru the receiving circuit, according to the researches of C. Mairan. The complete circuit is a combination of an insulated iron wire and a portion of the primary current effect from the receiving apparatus, the iron coil is used as a magnetic circuit. It is seen, therefore, that the effect is dependent upon the nature of the secondary circuit thus resulting.

It is evident, from the foregoing explanation, that at every incoming signal there will be a sound heard in the phones as the Hertzian wave current flowing around the primary coil cause partial cessations or reductions in the hysteresis effect produced in the moving of the wire band.

One of the most important circuits used with the Audion valve is that using one valve for producing an oscillating condition. This is shown in diagram Fig. 8.
ELECTRICAL EXPERIMENTER

The circuit as here shown has been successfully used for several years by experimenters and others without the tickers, these being designed to tend to stabilize the oscillating conditions, once they are set up by turning the various inductances and capacities. The condenser capacities are correct. It is suitable for intercepting damped as well as undamped signals. The inductances are of the following dimensions—primary of loose coiler is 10 by 5 inches, wound with No. 22 S. & S. wire; the secondary is 10 by 4 1/8 inches, wound with No. 28 S. & S. wire; the secondary is 10 by 9 3/4 inches with one layer of No. 30 S. & S. wire, while the wing inductance W1 is the same size with a winding of one layer of No. 30 S. & S. wire.

Beat reception with Audion amplifier connections has been accomplished with great success by Prof. A. Hoyt Taylor in the radio laboratory of the University of North Dakota. In his circuit, which has proved sensitive enough to pick up the German stations, 4,000 miles away; and shown diagrammatically at Fig. 9, is a model of two Audions, Nos. 1 and 2, both of which are chosen so as to be capable of generating oscillations. The primary transformer M (9,000 ohms) may be made from a spark coil secondary or a couple of them, thus a soft iron core wire is past, and the whole sealed up in a tight cabinet filled with molten paraffin wax or sealing compound. This inductance M, allows current from the 3-volt battery to pass but stops high frequency or pulsatry current. The stopping condensers SC should, therefore, be small, the second one being of about 0.5 millifarad and the first of 0.001 millifarad, or 0.0001 microfarad or 0.000001 farad. The variable capacity C should not be above 4 millifarads, thus permitting L to be large. For very long waves, up to 2000 miles was used; its average height was 75 ft., and its capacity 0.013 m. It. The circuit LC is slightly mistuned from the signals and the Audion filament becomes somewhat at times, normal, when working this circuit. The beat note is thus greatly amplified when it reaches the ear of the experimenter. Prof. Taylor has done excellent work with this arrangement, hearing the German stations at Nauen (10,000 miles wave length). Elwes (7,800 miles wave length) with both the arc and the spark signals sent out from the station at Honolulu, T. H.

(To be continued)

LOCATING AND DESTROYING "SUBS" WITH MAGNETS.

(Continued from page 6)

In operation, a fleet of ships are supposed to travel abreast towing their respective electro-magnets, and the moment any one of these is brought within the vicinity of a submerged metallic object, it will be attracted to such an object. The magnetic cables are then payed out to prevent any possible collision with the magnet cable from the object and in the meantime the ship may be brought to a standstill. In some instances the force of the powerful electro-magnet may be great enough to permit raising mines, by simply winding up the cables controlling the magnet and boom. In most cases, however, this is necessary, which may itself be fitted with a self-contained magnet, and exciting means such as a battery, would be lowered to destroy the empty tramp. There is a case on record that before exploding the bomb that the vessel should move off a safe distance to prevent injury to her hull, due to the terrific concussion waves transmitted by the explosion thru the water for a distance of several hundred feet at least, in most instances.

NEW SPY AND SCIENTIFIC MOVIES.

(Continued from page 8)

as the subject of a proof of his love and faith. Overhearing her acceptance of Leslie's proposal, the now half-raised Durand believes the time has come when he can execute his scheme of vengeance. Before a large crowd of scientists and family surgeons, Durand exiles is inoculated. Durand, stealing the key to the cabinet in which the precious serum is kept, destroys it, but in so doing inoculates himself by handling it. Health has been by occasioning the ailment germs. The time arrives for Laurel to administer the serum and she discovers the theft from the cabinet. After trying frantically to get out of Denver the Zoo, she dispatches her chauffeur with instructions to bring back the only other specimen of vaccination serum at all costs. Confronting Durand, she accuses him of the theft and he confesses. After an agonizing delay, the chauffeur returns with the turpentine and is able to save Leslie from a terrible death.

Meanwhile, her husband arises from a drunken stupor into which he has fallen and finds himself locked in a small room of the laboratory. By the time he is able to attract the attention of Laurel he has become seriously ill. The girl gives Durand the two remaining injections of the serum and Laurel is confronted with the choice of risking the life of the loves or saving her husband. She decides. Due to the fine vitality of the young physician, he fights a splendid battle with death and recovers, while Durand, whose health has been hapt by indicating the ailment germs, dies. After the scathing fires of fate to which she has been subjected, Laurel finally emerges happy in the love of young Leslie and together they plan a life devoted to the serving of humanity and the true affection which they now realize they have always borne for each other.

YANKEE CODE NOT SO "BLOEDSINNIG".

(Continued from page 7)

it never materialized into anything big. It is really wonderful tho, to think that he could transmit speech a distance of one-half mile by so simple an induction he used elevated wires connected at their upper ends to large condensers and at their lower ends to the earth. Thomas A. Edison also worked with the same apparatus, and the negative system of wireless between a moving train and a "paralleling circuit" string track pole point of view of the car was metal covered and the telephone apparatus was connected to it as well as to earth thru the car wheels. Success was at hand, but never became a commercial proposition.

ELECTRICITY AND METAL COATED SEEDS BOOST CROPS.

(Continued from page 9)

High frequency electricity produces a definite vibratory impulse that is doubtless the cardinal factor in increasing plant growth. The idea that the electricity primarily heats the ground is not a correct one. The heating may be incidental to other results, and
in wet, cool weather may serve to counteract inclement weather conditions. This, however, is rather incidental to the major point.

"That it enriches the plant life and stimulates the quality of the crop," says the inventor, "I have proved to my own critical satisfaction. The electrically grown plants were so much more succulent and sugar laden than the other variety that, aloft only six feet separated two sides. Dehydrated green plants were the choice of even that sugar-loving beetle, the 'astor bug.' When the superior quality of the plants makes even pests discriminate, the method has furnished at least its first credentials.

"Do you think the electric idea might be adapted to the extermination of insect pests?"

"Certain insects are susceptible to the electric vibration even in its present form," he replied. "The electric influence has been known to force worms out of the ground. I have little doubt that the ramifications of the idea will see electricity used not only to foster plant growth but to protect the crops themselves."

It is unqualifiedly affirmed by those interested in the tests that the electrical treatment of the seeds, roots and soil increases production so markedly that the beneficial effect of the treatment cannot be gainsaid. Adjoining fields of corn and sugar beets, planted at the same time as those specifically treated with the electrode current diffusers, showed growth and production only half the results as great.

The result of tests in electrifying corn and sugar beets on eleven acres of Illinois land, as announced by R. D. McCreery, follow:

**Electrified Corn**

- Increased the germination 31% to 39%.
- Increased the rapidity of growth 30% to 50%.
- Increased the volume of stalks 33% to 40%.
- Increased the corn production 30% to 40%.
- Increased the money value of crops per acre $25 to $35.

**Electrified Sugar Beets**

- Increased the production in weight volume 15%.
- Increased the sugar content 14%.
- Increased the money value of crop per acre over $50.

The cost was less than 50c per acre for current and metallically coating the seed. Net cost of apparatus installed was less than $200.

---

**A TIGHT SQUEEZE FOR UNCLE GEORGE.**

(Continued from page 39)

...when we leave the Temple of Thespis by the back entrance, it is necessary to climb a flight of stairs to handier to the car—also less handy to the public eye.

My invention consisted of alloying to the composition of the liveshows what hitherto were a "sister art!"; and my acquaintances with this sister, a modest violet now to be dragged into the garish light that beads upon the surface of a musical science."

The Riverside Press, in Cambridge, my native "burg," was a favorite prowling-ground for us kids. If you were good, and didn't chew gum, you could stand and watch one of the big presses squeeze a sheet of paper, haul it out covered with book-pages, and spank it down on top of a pile of previously printed ones, with an almost human emphasis that reminded you of the "There, thank goodness!" air of a woman ironing the last piece in the wash.

Sometimes the printer would give you a sheet of paper that was twisted by going in crooked, and you could read the middle eight pages of a detective story for nothing—though the combined love-story which both the crime and the detection extracted is very low in percentage of thrill.

Besides the printing, there were a hundred other processes visible, and each was so interesting that you never got very far in a single visit to the Press. Before you knew the words below, the machinery would slow down and stop, and the workman would thank you for your kind attention and depart to see if he could find a clean place on his desk.

One day, as I was exploring this palace of marvels, I came upon a workman over in a corner by himself, without a single power tool, and a lot of bottles. He was marking paper, and the barbaric richness of his product was enough to make you dream you dwelt in marble halls, as the song goes.

On the surface of his tank of water he sprinkled drops of brilliant-colored oils, he red, green, yellow, and vastest blues in the tinter. Each, as it struck the water, floated and spread out in a perfect circle. Scanned our eye, the beams of light swirled the surface with the simplest tools, the colored circles drew out, zigzagged, spiralled, scalloped, and finally came to rest in the intricate design of variegated marble. On this, a sheet of paper was gently let down, the oils adhered in an instant, and the design, as intangible as a bubble, was fact forever.

That was the invention which popt into my head at the theater—to project on the stage these new ever-changing designs, shifting every instant like the figures in a kaleidoscope.

The drawk speaks for itself—the invention's name was Simplicity. The tank, for blending the colors, was to be glass. The beam from a stereopticon, condensed by lenses, was to cast forward an image of the colored film, which a mirror would then reflect into a horizontal direction to flood the stage. The stirring of the colors was to be done by the beam of air through a blowpipe, to keep the cause of the changes invisible.

Fortune was mine—again. If the theatrical world would stand for that crude blue-and-star effect, unfavorable of the inventive powers of a semi-intelligent janitor, what sort of a thing do you think of in sight of my dizzying spectacle? Answer: once seen, it would be universally demanded. With the monopoly of the business in my grasp, I feel that I can be firm with Koyal, the Spectacle King of those days. He would probably try to get, for almost nothing, my invention which was destined to lift his shows absolutely out of the commonplace. The experiment had to be tried out, of course, and the janitor's purposes, and fortunately I had a small magic-lantern as so much toward the equipment. I made a tank from a window-pane surrounded by a wall of glass, and I had a janitor's workman at the Press, out of regard for Science (also, to some extent, for his own peace of mind) contributed an assortment of his liveliest pigments.

My lantern being lighted, and everything ready for the test, I scattered a few drops of the paint mixture, in my tank, blew gently across the surface thru a straw, and was delighted to see the colored dots mingle in bands like a Roman sash, or fancy forms of designs varied from moment to moment, all projected in a magnified form on the white-washed cellar wall.

So far, I had got by without exciting the...
family's suspicion of my dealings with the Powers of Darkness, the magic-lantern was a familiar household object, and I was always messing around with something or other. So, away to New York and confer my invention on the waiting public when the enterprise was wrecked—yes, absolutely wrecked—simply by extending my experiment to a wholly unnecessary realism.

At that time, my particular pal and partner in undertakings of magnitude was "Gimp" Smith, an old pal from my first school-days. The Skillingses were easy-going people, and Gimp was little harried by restrictions; in fact, he was free and easy, a prince of a man of the world, so far as it could be done on an income express in marbles and rusty nails, rather than money.

"Gimp," with his love for the theater, and his approval of my invention was enough to guarantee it in the winning class, he strongly advised adding to our equipment a model stage. It seemed superfluous to me, but "Gimp" was keen for it, claiming that Mr. Kiraly always required a stage in these business deals; in fact, it was the inevitable custom in theatrical circles.

That settled it, we went to work and built a small, neat, and solid-looking affair of soap-box-luxury, painted with a process arch and footlights, and hung with a series of cheese-cloth curtains. We reproduced the sensational finale of "The Big Things," a doll moves out of my sister's consented to assume the role of the Fairy Queen—standing, with white robe, magnificently draped, behind the innermost curtain, to be revealed at the critical moment, rescue the lovers, and save the "Crook" into his flaming pit.

The full-fledged rehearsals came off at 4 o'clock one Saturday afternoon. It was a winter day, and cloudy at that, so it was practically pitch-dark in the cellar, of course with the red-hot hearth. Gimp worked the stage properties while I handled the light. As I started the colors going, he raised the cheesecloth curtains, one by one, declaring the impressive climax of our favorite playlet—full of thee and thou's, with here and there a forsaken word. As the last curtain went up, exposing the doll in her fairy-queen rig, "Gimp" turned on the full power and said with a whispering voice: "Fear not, weak mortals, I will protect thee henceforth. And THOU, O Black Crook, down, down with thee to the nethermost torments of the damned." Whereupon "Gimp" opened the furnace door and threw in a lump of coal to represent the Crook.

Now "Gimp" was a word very much out of favor in those times. Its use was considered extremely bad form, so I thought that in the daytime at any time I would recite an appropriate speech:

"I'm not so weak, mortal, that I will protect thee henceforth. And THOU, O Black Crook, down, down with thee to the nethermost torments of the damned." Whereupon "Gimp" opened the furnace door and threw in a lump of coal to represent the Crook.

“SHOOTING” ELECTRICAL TROUBLE

caused by the burning of the contacts when the switch is allowed to open slowly and arc. During the slow and wand stopper, parts clean and replace. Should the switch reset O. K., the trouble will then be found in the wiring; it being either a short-circuit or a broken wire. In case the test in Fig. 7 shows no de- 
ded drop at the motor terminals over that at the commutator, with the starting rheostat, the trouble lies in the motor. This may be due to a number of causes as follows:

Motor brushes may be short, stuck, in the heart of the commutator, or improperly fitted to the commutator. Weak brush springs, dirty commutator or rotor commutator. Open circuits in the armature and low sections will be indicated by the burning of a few segments of the commutator.

Most of the above troubles will be detected by noticing the parts cleaned and corrected, always using fine sandpaper for cleaning the commutator or brushes. To fit the brushes to the commutator wrap a piece of fine sandpaper around the commutator and with the brushes pressing on it, turn the armature by hand till they are ground to the same curvature as the commutator.

A grounded armature can be detected by using the ‘phone test as shown in Fig. 14 A. A short circuit is indicated by a ground.

The work of removing the ground should be left to an experienced man unless you are well acquainted with armature work. The usual method is to reverse the rotor, which is removed itself disconnect the leads from the commutator at diametrically opposite points and then test each half of the winding. The winding is lifted apart and tested, till all the grounded coil is isolated. The coil is then raised from the core and the ground found by examination of the winding. Steps can then be taken to isolate or replace the coil.

A shorted or open coil can be found by testing the armature as shown in Fig. 15. As shown in Fig. 15 A, the two terminals of dry battery and leads brought out from both sides of the interrupter. These leads are made fastened in a leather strap that passes around the com- mutator. A receiver fitted with two pointed probes is used for making the test. One of the ends of the probes placed an adjacent segment, a segment note will be heard in the receiver. The en- tire commutator should be tested by shifting the probe from segment to segment and noting if every two segments gives the same signal strength in the ‘phone. A loud note between any two segments indicates that the coil between them is open, while no note or a very weak note shows a short-circuited coil.

Should the open be in the winding itself it can be repaired temporarily by bridging the two segments with a short length of wire or a drop of solder. A shorted coil will cause the commutator to heat and eventually burn out; it should be opened if possible, shorting the segments to which it is attached, as pre- viously mentioned.

A discharged battery may be due to the generator not furnishing enough current to properly charge the cells. A method to test for this trouble is to connect the ammeter in the circuit, as shown in Fig. 10. The meter will indicate the output of the motor and the cells. The meter should then be shifted to the reference shown in Fig. 11, and will then indicate the current actually delivered to the batteries. The readings should be the same, in both cases unless current is used for ignition, when an allowance should be made. Should the difference be reasonably large the trouble lies with the wiring or the automatic cut-out switch.

Where the vibrating type of regulator is used the contacts may become burned and blackened, causing the field circuit to increase in resistance or become opened. When cleaning or dressing regulator con- tacts be careful not to remove too much of the spring on which the contacts are mounted.

Should the machine fail to give the proper output the trouble may be due to any of the defects mentioned in connection with the motor. Open fields or armatures are sel- dom found in high-speed driving fields, being due mostly to faulty contacts on regu- lating appliances. The test for a genera- tor armature may be made in the same way as for trouble in the motor armature. Some cars are fitted with the motor and generator in one unit, but the method of testing is not varied on this ac- count.

The method for testing a single wire system for a poor ground connection is to cut the ground wires, as indicated in Fig. 11 A, and then drop a ground the connection is poor. The parts should be well cleaned and covered with white powder when testing is again performed.

A ground on a two-wire system can be detected as shown in Fig. 12, by using the ‘phone tester. A click in the receiver indicates a ground, and the various circuits should be switched off until the circuit giv- ing the trouble is found, and by tracing it out the trouble located exactly and removed. This can be done by testing with a leak detector as shown in Fig. 13, with all switches open. An indication on the meter shows a short circuit on ground, and the switches, which can also be found by tracing the wires.

This covers the field of automobile testing in a general way, and any trouble not mentioned can be readily located after be- coming familiar with the instruments. The proper care of the parts of the equipment will go a long way toward the prevention of trouble.

Care of Motors and Generators

Cleanliness is the first essential in elec- trical work. A clean motor and generator should be kept clean and free from dirt. Do not put any lubricant on the commutator, and in low-voltage machines you should keep the brushes clean and in good condition. Keep the brushes and commutators clean and see that they are kept good if the brushes are to move freely, and that there is sufficient spring tension to hold the brushes firmly against the commutator, even when undergoing vibration from the engine. The generator must be kept in good condition to properly charge the battery.

Care of Storage Battery

Add nothing but pure water to the bat- teries and do so often enough to keep the solution above the plates. Distilled water is preferable in this purpose, but rain water may be used if it has been in contact with metal for any length of time. Keep battery charged, taking hydrometer readings to check its condition at least once a week. Do not use the cranking system to excess. When the starter is used often it becomes necessary to give the battery a charge from some outside source from time to time.

Note the ammeter readings on the dash to check the battery. Any fall-off in the output should be corrected at once.

Continuous operation of the battery in an over-load may destroy the battery beyond repair, necessitating replace- ment of plates or of the entire battery. The only way is to keep the bat- tery fully charged at all times.

Free to You!

Read this Remarkable Offer!

This masterpiece contains 160 pages, 400 illustrations. Size of book 5" x 9". Printed on extra thin paper, so book can be slipped in pocket. Handsome stiff cloth cover. FREE with a year's subscription.

Remarkable Offer!

This is a very limited offer. It may be withdrawn at any time, due to the tremendous cost of paper, which IS JUST DOUBLE WHAT IT WAS ONE YEAR AGO. We only have about 2000 each of these fine books on hand; after they are gone we cannot reprint the books until conditions become normal again. THIS MAY BE TWO YEARS OR MORE. Now is your chance.

The publishers of this journal have earned an enviable reputation of giving more than 100 cents' worth for each dollar spent with them. Prempt by this liberal opportunity NOW; it may never be made again.

HERE'S THE OFFER

Subscribe to THE ELECTRICAL EXPERIMENTER for one year, at the regular subscription price of $1.50 per year (Canada, foreign and N. Y. C. $2.00) and we will send you FREE POSTPAID, either one of the above books. If you subscribe for two years, BOTH BOOKS WILL BE GIVEN FREE, POSTPAID.

If you are a subscriber at present, take advantage of this wonderful opportunity anyway, if you do, we will extend your present subscription for one year.

This Offer Limited. Act Now.

SCIENTIFIC EXPERIMENTAL

MISCELLANEOUS

HARD RUBBER JARS for automobile storage batteries, per dozen, $1.25. For sale at H. Theron Co., 203 S. Main St., Michigan.

INVENTORS! ATTENTION! I have valuable information you can protect your inventions for years before patenting, without expense or risk, full instructions, 25c. H. R. Lambert, 55 Willow Ave., North Pelham, N. Y.

AEROPLANE—Curtiss number type $300, or complete with motor $1,700.00. For photo and descriptive write H. A. Margrete, Kirkville, Me.

C R E D I T W R I T E R WITH PATENT RIGHTS. Patenting a patented small article, likely good seller, one each. No money down, having signing rights on device or want to patent or sell. Not answering cranks. John H., 1563 Annapolli St., Honolulu, T. R. U. S. A.

SELL—Large wireless receiving set, boy's books, maps, country, 22 cents, toys, motor, $2. Ernest Sarness, Martinsville, N. J.

FOR SALE—Swinifl Watch Co., printing press and type. Size, condition and price in first letter. Have phonograph parts, low voltage transformers, etc. Rola. J. Hedstrom, Racine, Wis.

FOR SALE—Senea Plate Camera, 4 by 5, and full equipment. Good as new. First money order for $75 makes it. Particulars free. Rannels & Rannels, Portland, Oreg.

BARGAIN—Will sell Smith Motor Wheel, which has been run only 10,000 miles, for $30 cash. Terms C. O. D. Smith, 106 S. 11th St., Davenport, Iowa.

FOR SALE OR EXCHANGE—One latest improved 12 inch belt motor pulley cleaner, complete with tools and 120 ft. steel re- ing tool in box. Use also on two-wheeled cart; cost $365, sell for $180, or have you to trade. Particulars free. J. H. Vogt. 113 E. 88th St., Chicago.

BARGAIN—Will sell Smith Motor Wheel, which has been run only 40,000 miles, for $30 cash. Terms C. O. D. Smith, 106 S. 11th St., Davenport, Iowa.

FOR SALE OR EXCHANGE—One latest improved 12 inch belt pulley cleaner, complete with tools and 120 ft. steel re- ing tool in box, used also on two-wheeled cart; cost $365, sell for $180, or have you to trade? Particulars free. J. H. Vogt, 113 E. 88th St., Chicago.

DEAD RISING—Bundled 100 pounds each, per dozen, 30c. Have tools and supplies to exchange. Simple and effective. "New Process," 670 Fulton Street, Grand Haven, Michigan.

WE HAVE FOR SALE the following Revolving Armatures and Instruments, including: 10,000 volts, 2,200 volts, 6 phases, 60 cycles, 600, 53 amperes per terminal, complete with sliding plate, pulley, exciter, and switchboard complete with ammeter, voltmeter and controlling devices. Exciter is 3 K. W. 1,200 watts; serial number of generator is 779846, Price $2,000.00. Kindly advise at once if interested. Wishing to make a pair for a friend, a patent has been made. Binzel-Spake & Auto Wheel Co., Portland, Tenn.

WE HAVE A LIMITED number of beautiful art pictures on hand of Nikola Tesla, and Dr. Lee de Forest. Both are in pictures, and are certain. These can be made. Binzel Spake & Auto Wheel Co., Portland, Tenn.

EVERYTHING IS FOR SALE, all kinds of things, large and small, of the best grade of quality. The complete remnants of a shop. A real Bargain for less than 50c.

THE CLASSIFIED COLUMNS of the "Electrical Experimenter" Bring Positive Results.

Subscribers experiencing trouble in dealing with the publisher very promptly.

OVER 100,000 PEOPLE READ THIS JOURNAL.

A RELIABLE ELECTRICIAN working or interested in the electric line. Apply to the publisher.

EXPERIMENTER Publishing Co., 233 Fulton St., New York City.

"WANT TO SWAP"?

Do you realize that these "Scientific Experimental Columns" are the very ones that are now read by over 100,000 people? Will you sell your old and receive new for free? There is no more logical way to exchange. The old ones" being interested you will be in a position to sell them to someone else. At a ridiculously low cost you can either sell or swap such articles.

And remember this fact: The U. S. Postal Laws prevent you from swamping this journal. You of, 3,000 "ads" published in these columns during the past five years, only twelve complaints were reported against us, and each of these was disapproved of by the full satisfaction of the complainant.

It matters not if you have old books or magazines, a lab.-or even any electrical apparatus, scientific instruments, bicycles, typewriters, moving picture machines, air rifles, wading shoes, etc. All kinds of things are wanted, and these and countless others are speedy SWAPPED or sold. You will have a valuable trade to dispose of.

FOR SALE—First $15 takes No. 3 Emerson typewriter. Slightly used. C. E. Foster, Junias, Nebr.

FOR SALE—Electro Varioc Selective Coupler (new), $5. Wm. Liddick, Hackenack, N. J.

BARGAINS—Cabinet Receiving Set, Audion, Leduc, & Vickers. Complete with box, key, Saucer, etc. Write for list and prices. Harold Spencer, East Concord, N. H.

FOR SALE—6 H. P. 4 cylinder 4 cycle gasoline engine with motor and carburetor, $27.50. Frank 3061 Meridian St., Indianapolis, Ind.

Buy our "50c" Portable Speaking Book "Michael Faraday, His Life and Work" by Sylvanus Thompson. Also an outline of the Roller-Shaft type and a Wheatstone bridge; must be in first-class condition, and include galvanometer. H. W. Secoy, 6th Electrical Experimenter, 25 1/2 Stanton St., New York City.
EVERY electrician, every engineer, every mechanic should have one of these wonderfully helpful instructive books, which give in plain words a complete working knowledge of electrical engineering in all its phases. You run into some new electrical problem almost every day. The information you need to help you in your every day work is in HAWKINS ELECTRICAL GUIDES.

These books place electricity at your finger ends. They cover every imaginable subject, principle, theory, problem, trouble, and way of doing things electrically. Every subject is indexed so that you can turn right to it. They are a study course and a reference guide in one, written in plain everyday language—no wasted words—just what you need to know—packed full of up-to-the-minute electrical knowledge. The guides are a complete course in electrical engineering. They will help you in every detail of electrical work. You can't ask an electrical question that Hawkins Guides can't answer.

Pocket-Size Flexible Covers

The books are small enough to slip into your coat pocket—handsomely bound in flexible black covers.

You can carry each volume with you until you have mastered its contents, 3,500 pages of actual information and 1,075 illustrations. Once you see these books and read their covers again want to be without them. Try it at our expense.

SEND NO MONEY

It will cost you nothing to receive these books—to look them over—and then all the operations you can think of—use them in your work—study them—pick up some information that will increase your earning ability. We will ship you the entire set of 10 volumes outright FREE.

This is a sign of our confidence in the guides. Page gold does not object to being tested. Keep them for seven days and if you do not decide that you can not get along without them, return them to us and owe us nothing.

When you decide to keep them you only have to pay $1.00 down and remit the balance of $9.00 on the exact same day.

Use this coupon to get the books. It will pay you many times over.

Better Pictures—Less Bother

I received your Mandel-ette outfit yesterday and after retorting it out today I must inform you that I have taken some pictures that cannot be done with it. The first three pictures that I took were better than most of the snapshots that I took with a fancy camera, and there is no need be better and work in making the pictures. I have shown this to a great many people today and I am sure that you will be able to sell at least 5 or 10 here if I had some way of demonstrating the people. I am going to show my outfit to everyone I meet and I am sure you will be able to sell 5 or 10 in the next few months.

WALTER G. HERMAN, Newburg, Ore.

Surprised At Fine Pictures

I am making some fine pictures with no trouble at all. All who see my Mandel-ette Camera say that it is fine and they are surprised when I make a perfect picture in one exposure.

J. H. DUNN, Pediatric Staff, M.

Wouldn't Sell It At Any Price

I received your Mandel-ette and am much pleased with it. I took some pictures and even though it was a cloudy day, they came out just right. I wouldn't sell the camera at any price.

MRS. KINSEL, Gloucester, N. J.

We Trust You

No difference who you are, where you live or what your age, we will send you the complete Mandel-ette outfit absolutely on approval and give you ten days to test it. If not satisfactory return it. But when you see what elegant pictures it takes—it so quick, so easy, with no trouble at all—if you wish to keep it you simply send us $1 per month until our special price of only $5.50 is paid.

Easy Payments—No Reference

No red tape of any kind. Monthly payments so small you'll not notice them. Simply fill out and send coupon today. No references required. Lots of fun and big profits.

Chicago Ferrotype Company,
Desk 223 Ferrotype Bldg., Chicago, Ill.

Send me one complete model Mandel-ette outfit including supply of post cards and instructions. I agree to examine and test it thoroughly and if satisfied pay you $1 a month until your special price of $5.50 is paid, otherwise I will return it at the end of 10 days.

Friend Sends Order

My Mandel-ette arrived early last Saturday morning O. K. Thirty minutes after it arrived I took my first pictures and it was a perfect success. I am sending your sample outfit today and I by you will pay for itself in two hours. Enclosed find order for more.

J. H. BONETCUTT, Edor, N. C.

No Chance For Mistake

Your special outfit reaches me by express this morning. It arrives all right and I then there is no danger of any accident in transit, as the first picture I took was of my wife and children and it is the best I have ever taken. That was the first time in my life that I have been able to take a picture, in fact, it is the first time that I have ever used a camera of any kind and by following your instructions in the circular there is no chance to make a mistake.

TOMMY WEST, Louisville, Ky.

$18.00 In Two Days

I wish to say that I am well pleased with your outfit. I have been in the photographic business work at the Centennial County Fair. I have made about fifty for with my Mandel-ette and today I sold twenty. I paid for itself in two hours. Enclosed find order for more cameras.

J. J. HURRICAN, Jr., Elkhartville, Tenn.

Make It Pay In 2 or 3 Hours

I received your camera O. K. and am well pleased with it. I have had time to look it over and I have never found a camera that works better. I will pay for itself in two hours. Enclosed find order for more cameras.

J. B. HONEYCUTT, Edor, N. C.

Camera Success—Want Agency

As I have bought five of your Mandel-ette outfits I will be happy to pay for all the pictures I take. I wish to speak to some of your paying agencies to become your agent. I have several young men here who are anxious to buy one and I will send you their names as soon as I return to you.

GEO. HENDTIC, Ft. Collins, Colo.

More Than Paid For Itself

I am very pleased with the Mandel-ette Camera. I have made some very good pictures with it and it has already made more than paid for itself.

CHAS. E. MEARS, Jasperville, Ind.

MEN WANTED AS
CERTIFICATED ELECTRICIANS

This is the Electrical Age, and this wonderful new profession is calling you. The demand for expert Electricians is greater every year and the salaries higher. Electricity is truly the greatest motive power in the world, to-day, and now is the time to enter this profession.

YOU CAN DO THIS
AFTER HOME STUDY
$36.00 TO $100.00 A WEEK

You can earn $36 to $100 a week and more as an Expert Electrician. If you have a common school education I can train you in a few months at home. Big lighting and power companies, municipalities, and manufacturers are always seeking trained men to handle their Electrical problems.

I Guarantee Satisfaction
Every student receives our Sealed Guarantee Bond, which guarantees to return every penny of his money if he is not entirely satisfied. No other school has made this wonderful offer, but I know the success I have brought to hundreds of my students, and I know what I can do for any ambitious young man who will give me a little of his spare time each day.

$5. The Boy's Electric Toys

This is an ideal battery for electrical experiments with a very potent current is not required. This battery will last as long as a lamp for several hours on one charge; it will run a small toy motor, ePub; it is a marvelous toy! As such it will be of great use in so many electrical experiments; it is ideal for building small telephones, signal lights, etc. The apparatus, no materials are used when building the apparatus.

No. EX200 Experiments... £5.00

... The Boys Electric Toys

$5.00

The "Electro" Radiotone

HIGH FREQUENCY SILENT TEST BUZZER

This instrument is a wonderful high pitched MUSICAL NOTE in the receiver, impossible to obtain with the ordinary test buzzer. The RADIOTONE is built along entirely new lines, is entirely different in construction from any ordinary circuit. The RADIOTONE has a single rod, free from binding, adjusted to its most efficient frequency at the factory, too cheap to use and too nice for the instrument. It is sizeable to exhibit.

You, the RADIOTONE is SILENT. In fact, it is so silent that you must have your ear on top of it to hear it. It is a practical instrument, as you will be astonished at the wonderfully clear, 500 cycle note, sounding through the receiver. For a receiver, reason for silence, too sensitive, and too perfect, is the curve of the receiver's set is now. Two or more such sets in series will afford no more of pleasure for intercommunication... Price Complete as Illustrated (TWO INSTRUMENTS) & $1.25

The "Electro" Telegraph

Is not a toy, but a practical, honestly built telegraph outfit, which not only sounds but works like the big commercial instruments. By using this instrument you can learn all about the working of a first-class telegraph operator. The apparatus is in the usual form, but we have added a new circuit. Outfit consists of two transmitters, receiver, key, code chart, and instructions, illustrated. This instrument can be used as a wireless receiver, or as an experimental instrument. Two cells can be used with set, but no batteries. Outfit works on any instrument. The "Electro" telegraph outfit that works both ways, each station can call any station, no extra station to get on, no wires necessary. Price Complete as Illustrated (TWO INSTRUMENTS). & $1.50

The "Electro" Codophone (Patents Pending)

This Codophone is a handsome, well made instrument, it is patented, and can be used as an intercommunication instrument or a telephone. The Codophone uses two dry cells, and can be used for intercommunication between two stations, and also as a wireless Maxwell Codophone, illustrated. The Codophone is a complete, & $1.50

The "Electro" Codophone and Telegraph

This outfit contains 114 separate pieces of material and 24 pieces of finished articles ready to use at once. Among the finished materials are included: Chrome plates, lamp socket, battery mercury, copper wire (two different lengths), a bottle of iron filings, three spools of wire, carbon, a quantity of machine screws, flexible cord, two wood bases, glass plate, paraffin tube, binding posts, screw driver, etc. The instruction book is in clear style that anyone can make the apparatus without trouble, and besides a section of the instruction book is taken up with the fundamentals of electricity to acquaint the layman with all important facts in electricity in a simple manner.

We guarantee satisfaction.

The over all of the outfit is 14 x 9 x 2%. Shipping weight, 8 lbs. & $5.00

No. EX200 "The Boy's Electric Toys" outfit as described... £5.00

ELECTRO IMPORTING CO. 231 Fulton St. NEW YORK
AVIATION MECHANICS
Needed for New Positions

Thousands of splendid new positions now opening up everywhere in this amazing new field. New Airplane factories being built—automobile and other plants in all parts of the country being converted to turn out vast fleets of Airplanes for our armies in Europe. And only a few hundred expert Airplane Mechanics available, although thousands are needed. And this is only the beginning. Already airplane mail routes are being planned for after the war and thousands upon thousands of flying machines will be wanted for express and passenger carrying service.

Not in a hundred years has any field of endeavor held out such wonderful chances to young men as are offered to you today in the Aviation Industry. Resolve now to change your poorly paid job for a big paying position with a brilliant future. Send the coupon today for Special limited offer in Practical Aeronautics and the Science of Aviation and prepare yourself in a few short months to double or treble your present salary.

We Teach You By Mail
IN YOUR SPARE TIME AT HOME

Our new, scientific Course has the endorsement of airplane manufacturers, aeronautical experts, aviators and leading aero clubs. Every Lesson, Lecture, Blue-Print and Bulletin is self-explanatory. You can't fail to learn. No book study. No schooling required. Lessons are written in non-technical, easy-to-understand language. You'll not have the slightest difficulty in mastering them. The Course is absolutely authoritative and right down to the minute in every respect. Covers the entire field of Practical Aeronautics and Science of Aviation in a thorough practical manner. Under our expert direction, you get just the kind of practical training you must have in order to succeed in this wonderful industry.

Special Offer NOW! SEND THIS COUPON TODAY

It is our duty to help in every possible way to supply the urgent need for graduates of this great school. We have facilities for teaching a few more students, and to secure them quickly we are making a remarkable Special Offer which will be withdrawn without notice. Write today—or send the coupon—for full particulars. Don't risk delay. Do it now.

MAGNETIC STORMS AND WINDS

NE of the most puzzling scientific phenomena is the so-called local magnetic storm. Much has been written about this subject and many theories have been advanced, none very plausible.

Of late Professor Francis E. Nipher, of the Academy of Science of Detroit, the distinuished scientist who demonstrated experimentally gravitational repulsion—has shed new light upon the subject. Professor Nipher who, as is well known, is not a theorist, always supplies experimental evidence when announcing new scientific discoveries. Such being the case, and bearing in mind that the professor is an exceedingly exact and painstaking worker, it will come as somewhat of a shock, that an ordinary wind is one of the direct causes of local magnetic storms. At first blush, this sounds most preposterous, for who ever imagined that the motion of the air could possibly influence a magnet? Nevertheless it is a fact supported by a wealth of experimental evidence.

Professor Nipher began by reasoning that the magnetic force of a bar magnet might be diminished by draining negative electrons from it. He actually accomplished this by means of a static machine. Then it was found that while a needle carrying a magnetic needle during a wind storm in which sudden and violent wind-gusts occurred, the oscillations of the needle were suddenly and greatly changed. Careful and exhaustive experiments were subsequently carried out at Professor Nipher's home, at Hessel, Michigan, in a tent 50 feet from Lake Huron. The magnetic needle was a piece of knitting needle 7 cm. long suspended upon an unspun silk fiber 40 mm. long. The enclosing case was a large glass bottle, entirely airproof, so that no atmospheric disturbances could possibly reach the magnetic needle. Attached to the latter was a small mirror by means of which the motion of the needle was observed in the usual manner with a telescope and scale. A number of elaborate precautions (by means of control magnets) were taken to make the needle as independent as feasible from the earth's magnetic field, as well as preventing mechanical shocks from reaching the suspended and magnetized needle.

It was then found—and a mass of proofs exist to substantiate the facts—that on days when the wind blows in gusts at intervals of 1 or 2 minutes, the needle is more unsteady in its motions than on quiet days. How the needle predicts a gust of wind is best seen in the following occurrence:

At 1:10 P.M. on July 14, the needle began to vibrate to and fro, continuing in its motion for 9 minutes. Then a sudden and violent gust of wind came in from the lake to the south, overflowing a sail-boat lying 200 feet away from the observation station. About 8 minutes later the wind had practically ceased, and the oscillations of the needle had ceased as well. Many similar observations were made during the summer, all with the same results.

Professor Nipher's explanation of this strange phenomenon is that a wind disturbance, such as a tornado, among the atmospheric ions, which accumulate along the magnetic lines of force, at or near the earth's magnetic poles, is responsible for some of our widespread magnetic storms. Of course a small wind disturbance could hardly produce more than a small local magnetic disturbance, but it certainly does exist. But the wind along the sail is the real cause of local magnetic storms. The rain as well as cloud shadows produce the same effect. Thus when small clouds are scattered over the sky and a local fall of rain, the sun is at the observation station, the sunlight passing thru the air thru which the rain drops fall, a very marked magnetic storm results.

Furthermore, when the sun is hidden by clouds, the needle usually remained undisturbed. But as soon as the sun came out the needle at once began to oscillate markedly.

In an article of this kind it is impossible to present the full evidence of Professor Nipher's experiments, but it is quite apparent that local variations of the earth's magnetic field are determined wholly by local weather conditions.

Discoveries such as these tend to show how very incomplete our knowledge is as yet of magnetism and how much there remains for us to learn.

H. Gernsback.
'LEARN BY DOING'
The Only Way to Learn Electricity

The only way you can become an expert is by doing the very work under competent instructors, which you will be called upon to do later on. In other words, learn by doing. That is the method of the New York Electrical School.

Five minutes of actual practice properly directed is worth more to a man than years and years of book study. Indeed, Actual Practice is the only training of value, and graduates of New York Electrical School have proved themselves to be the only men that are fully qualified to satisfy every demand of the Electrical Profession.

At this "Learn by Doing" School a man acquires the art of Electrical Drafting; the best business method and experience in Electrical Contracting, together with the skill to install, operate and maintain all systems for producing, transmitting and using electricity. A school for Old and Young. Individual instruction.

No previous knowledge of electricity, mechanics or mathematics is necessary to take this electrical course. You can begin the course now and by steady application prepare yourself in a short time. You will be taught by practical electrical experts with actual apparatus, under actual conditions. 3,000 of our students are today successful Electrical Practitioners. Come in and read their enthusiastic letters. Let us explain this course to you in person. If you can’t call, send now for 64-page book—it’s FREE to you. SCHOOL OPEN ALL SUMMER.

New York Electrical School
29 W. 17th St., New York, N. Y.

Please send FREE and without obligation to me your 64-page book.

An Electric Aeroplane Shooting Gallery

A LL aboard for the electric aeroplane shooting gallery—three shots for a dime! Right this way, Gents. Wing a "Boche" plane in flight! This may be the speech that greets you in the large amusement parks this summer. We predict it will make a sure-hit with the amusement-seeking public, men, women and children. This recently patented contrivance is intended to give one all the sensations of actually shooting at a moving target, in this case a miniature aeroplane, from an aeroplane in flight. As the inventor, Mr. Frederic W. Thompson, points out, considerable skill will be required of the marksman to hit the moving target for the reason that the platform on which he stands will be constantly pitching and rolling, and moreover, the captive plane can be made to roll just like a real one, in two directions, i.e., up and down from side to side, and back and forth from front to tail. The whole arrangement is very cleverly designed so as to require the minimum of power to actuate it, and small electric motors do all the work of putting the flying machine thru her paces. It's quite a trick to hit a bull's eye from a moving plane, especially with a single bullet, which is quite different than the case of the regular army aviator, as there the gunner has the use of a rapid-fire machine gun which fairly sprinkles the air with bullets for a considerable area, and even then the enemy flyers do get away without being hit. In order to accomplish the desired re-

(Continued on page 132)
Moving Pictures That Really Talk

By GEORGE HOLMES

NOT so very long ago the world was startled with a new wonder, the cinematograph or motion picture as it is now known. Its rise has been phenomenal until now the “movie” business is one of the first in the

land and the aggregate capital runs into the
millions. In its present form it has done
much to relieve humanity of its cares and
worries, and for a nominal sum one may
take his family to a theatre and pass a
pleasant evening.

Nevertheless, inventors saw that there
were more possibilities in the “films” than
just a plain black and white picture; there
were those who thought that in time the
movie would eventually rival the spoken
stage, and to this end countless men have
been applying their time, money, everything
to secure films that would be clear, sharp
in Nature’s own colors and last of all—with
speech in perfect synchronism!

Color-photography has lately been real-
ized by a prominent inventor, and now
comes Mr. Eugene Lauste, a French in-
ventor, who evidently can lay claim to hav-
ing perfected a successful method of tak-
ing and reproducing “talking movies” that
are well nigh perfect, both as to tone and
synchronism.

Coming as this does from one who since
childhood has dreamt of this great ideal,
and made a persistent study of this great
art, one may have expected a great deal
from Mr. Lauste who was born in Paris in 1857. At the tender age of ten when only a mere boy he conceived the idea of "motion pictures." Taking a
strip of paper from the “Wheel of Life” or
Zenotrope, he soaked it in oil to make it
transparent and then pulled it thru a magic
lantern in a series of jerks. Of course, this
was very crude and at first no conceivable
idea could be drawn from this procedure
till one day, while adjusting the machine

another picture is drawn into place. So ob-
sest was he with the idea that from then
on it might be said that he has made it his
life work.

It might not be amiss to give a brief his-
tory of Mr. Lauste’s work in that it will
add weight to his claim of having invented
a real “talking movie.” From 1886 to 1892
he was associated with Mr. Thomas A.
Edison, first at New York and later at the
Menlo Park and Orange, N. J. laboratories.

While there in the year 1887, the Edison
Kinetoscope first saw the light of day. It
was not a projector nor did it have any
form of escapement. The film ran continu-
ously behind a peep hole and the pictures
on it were viewed directly by means of a

Specimen Record of Voice (Top) and Motion Picture (Bottom) Photographed Simultaneously.

The Voice Record is Made By a Strong Arc Light and Galvanometer. Reproduction of Speech is Caused By Light Acting On a Special Selenium Cell.

atures of the regular size. From Edison he
went to the Westinghouse Company, and
from there to the Eidoloscope Company.
Next he was associated with the Biograph
Company, where he worked the giant
cameras of the early pioneer days. In 1897
he went to England to show the Biograph
Films.

During his wide and varied career Mr.
Lauste has met and become acquainted with
many noted persons, among them being Mr.
M. J. Marey, a Frenchman, who might have
received the honor for the invention of the
cinematograph, had he foreseen the possi-
bilities of his "Photographic Gun" which he
built in 1876. It was not primarily intended
as a motion picture camera and therefore
he cannot lay claim to the title of father
of the Cinematograph, which might other-
wise have been his.

In operation the “gun” was much the
same as an ordinary gun, except that in-
stead of shooting bullets when pulling the
trigger, a number of instantaneous photo-
graphs are recorded at very short intervals.
The Marey gun has been resurrected during
the present war and is used extensively for
taking military photos from aeroplanes.

Mr. Lauste’s talking picture system is
somewhat apart from the method which
was tried several years ago and which no
doubt many people recollect, in that in his
system no phonograph and phonographic
methods are employed either in taking the
picture or in the reproduction. In this new
method a selenium cell and telephone sys-
tem are used to reproduce the sound direct-
ly from the photographic film. The film
passes continuously in front of the selenium
cell and no stylus or contact of any kind
is necessary. The sound waves are repro-
duced with utmost clarity and fidelity and
since these sound lines are directly on the
same film as the photo images, a perfect
synchronism is the result.

In the making of the “talking movie” it
is not necessary for the players to talk
into a horn as in the phonographic movies,
for a number of sensitive microphones are
distributed about the scene out of range
of the camera or else suitably screened as
in a flower vase, etc., to record the sounds,
and the players not being remanded con-
stantly by large horns or otherwise are
able to move about and do their business.

The sound waves are transferred from the
microphones thru wires and a storage
battery to a highly sensitive string galva-
nometer or oscillograph. The string or
sensitive wire is suspended in the field of
powerful electro-magnets and a very slight
variation of the electrical impulses trans-
mitted from the microphones is sufficient
to set the wire in motion. A beam of light

At Last! A 20,000 Shot per Minute Electric Machine Gun

HAVE you ever thrown the hammer at athletic events? If so, then you have a correct idea of what centrifugal force is, the force, so physics teaches us, which bursts flywheels as well as speeding the athlete's weight, all due to the fact that a revolving body always tends to lengthen its radius of rotation. That is, it tends to fly outward on an ever-expanding circle.

A Boston inventor, Mr. Levi W. Lombard, has brought forth a new death-dealing marvel which may prove of inestimable value to the Allies. It is nothing less than an "electric machine gun" which can hurl forth a perfect rain of bullets at the rate of 20,000 shots per minute or more.

It is therefore practically noiseless, smokeless, barrel-less and fool-proof. It has no barrel, which, is decidedly a good feature in this war, rendering it far less conspicuous than other guns provided with barrels.

Tests are said to have proved the gun's high efficiency. The new weapon has no barrel, operating on the principle of a sling.

FRENCH WAR CAPTIVES TURN HUMORISTS.

The accompanying illustration shows one of the humoristic silhouettes made by French soldier artists interned in Switzerland. It shows the Kaiser in one telephone booth and a figure representing God in the opposite booth. Evidently the Generalissimo of the "Potsdam gang" is carrying on a long distance telephone conversation with his much vaunted co-ally, "Gott," while the "Boche" guard stands at attention. If the allied army keeps up its good work of annihilating the Hun troops the private telephone line between "Me und Gott" may become much overheard; in fact, so much so that the "fuse" may blow out, leaving the Kaiser and his Potsdam miners in utter darkness so far as spiritual light is concerned. In fact, we have a strong impression that the "fuse" blew out when that 76-mile shell hit a church in Paris, killing about a hundred innocent women at worship, and we'll aver, too, that it wasn't the Kaiser's talk that overloaded the line and blew the "fuse."

The latter operates under a disc which revolves at tremendous speed. The ammunition is fed thru a funnel-like attachment from a tube which leads into two veins beneath the disc as the drawing herewith shows, and so rapidly does the gun consume bullets that the services of an operator are necessary every moment in order to keep the ammunition hopper loaded with steel missiles.

The veins center upon an opening about two inches wide and the bullets are thrown with terrific velocity. Electricity, gasoline or steam engine is the source of energy. The weapon can be placed in first line trenches and operated hundreds of feet in the rear, simply by the connection of an ammunition feeding appliance, the steam pipes or electric wires and a simple attachment for the changing of the machine's range. The inventor states that in a recent test the gun demonstrated its force and accuracy by firing hundreds of bullets into sheets of steel plates, three-quarters of an inch thick, placed hundreds of feet away. Many of the bullets went thru the plates. As high as 33,000 shots per minute can be fired with this gun, its inventor claims.

Referring to the illustrations herewith, the Lombard electric machine gun has a two- grooved disc as shown, revolved by a motor at 10,000 revolutions per minute or higher. This causes two bullets to be released thru the 5° slot in the casing at every revolution or 20,000 shots per minute. Tests have shown that bullets leave the gun at a velocity of 2,000 feet per second. The steel plate here shown is 9/16 inch thick and was penetrated by bullets fired from this gun. The bullets come out in a spray 5° wide, which can be aimed as desired.

The University of California is teaching farmers to use electricity. In the near future the indications are that the efficiency of electricity on the farm will be generally recognized and adapted.
A 100 Mile Electro-Magnetic Gun

Great Guns!!! That's what everyone is talking about these days, when the Teutons have succeeded in hurling nine-inch explosive shells into the heart of Paris from a monster cannon located at a distance of seventy-six miles away, safe within the German lines. The bombardment of Paris was started with two of these super-cannon, which were presently spotted by Allied aircraft observers as being situated in the Forest of St. Gohain, west of Laon. The first shells landed at intervals of about twenty minutes and did considerable damage to buildings, but caused relatively few casualties. At first it was thought that possibly enemy "bombing planes" were being utilized, flying at very high altitudes of say 25,000 to 30,000 feet, which, when properly camouflaged, would defy detection from the ground. When the Allied air scouts located the gigantic guns, however, it became evident that the wily Germans had conceived and executed another psychological grand-stand play in the form of a cannon that could actually bombard Paris from within their lines. The longest range attained hitherto with the standard 16 and 18 inch naval and coast defense guns has been in the vicinity of 25 miles. Ordnance experts have shown, however, that were it possible to build a successful 16-inch gun carriage...

This Illustration Shows Vividly the Great Altitude Attained By a 76 Mile Shell, Viz., 18 miles. The Shell Encounters But a Small Fraction of the Air Resistance in the Rarefied Upper Strata That Short Range Shells Do in the Lower, Denser Air Strata.

The Illustration Herewith Shows a Mighty 95-Foot Electro-Magnetic Gun, Capable of Hurling a Torrent of 19-Inch Shells, Each Containing a Charge of High Explosives. It Would Be Noiseless and Smokeless, Besides Being Mobile Enough to Permit Its Transportation From Place to Place at Short Notice. There Would Be No Wear and Tear on This Gun As Is the Case Now With the Cannon Using Explosive Charges to Expel the Projectile From the Barrel. First Described in This Journal For November, 1918.

All Illustrations Copyrighted by E. P. Co.
A report from Geneva, Switzerland, contains the statement that Lieut. Gen. von Robine, a German authority on ordnance and inspector of artillery, gives in a magazine of which he is editor additional details in regard to the long-distance German guns with which Paris is being bombarded. He says they are 20 meters (65½ feet) long. The empty shell weighs 150 kilograms (330 pounds). The projectile attains a height of 30 kilometers (18.6 miles) and descends from the sky like a meteor on its target. Refer to the accompanying illustration showing the trajectory of the projectile and how it passes thru the highly rarefied air encountered at such altitudes, the air pressure at this height varying from a fraction of an ounce to several ounces per square inch, this greatly reducing the air resistance offered the projectile in its flight thru the air, which possesses a very much greater density at low levels, the air pressure at sea level being 14.7 lb. per square inch. Even ordinary, long-range heavy ordnance fire as used today has to waste a great part of the energy given to the projectile in overcoming air resistance, the average shell traveling at say 2 miles highest altitude, for example. Now, at 2 miles the air pressure is still quite high, being 9.8 lbs. per square inch.

Gen. von Robine further says it requires about three minutes for the shell to reach its destination. The greatest difficulty in the way of increasing the range was overcome by sending the projectile high enough to reach the rarefied air.

The whole secret of such long range cannon fire lies in the elimination or suppression of atmospheric resistance, and hence it will pay us to study this subject of rarefied air in the upper atmospheric strata. The illustration showing the trajectory of the 70 mile shell also gives a clear idea of the make-up of the atmosphere surrounding the earth. The thickness of this atmospheric envelope has been variously estimated at from 30 to 50 miles. Modern researches have indicated that the earth’s atmosphere may be broadly divided into two portions,—a lower portion or stratosphere as illustrated, in which the chemical percentage composition remains tolerably uniform, since the mechanical mixture of its gases is maintained by winds and convection currents; but the pressure and temperature, however, fall as we rise upwards; and a second or higher region, the stratosphere beginning at a height of about 10 miles, when temperature ceases to fall and becomes nearly constant for an unknown further height. The lower region or troposphere is the locus of clouds and water vapor. Above the 10 mile line, in the stratosphere, the atmosphere is in a state of perpetual calm, the gases composing it actually sorting themselves out in order of density. The highest upper regions are composed entirely of the lighter gases such as hydrogen and helium. Above 45 miles the air becomes so rarefied it has no appreciable weight. Hence the struggle of heavy ordnance designers to build a gun that could be fired at the angle giving the maximum range or 43½ degrees, and thus project the shell rapidly into the highly rarefied strata of the upper atmosphere.

There have been a number of designs for powerful electro-magnetic guns brought forth by various inventors in the past 15 years. One of these electro-magnetic cannons, here pictured, was described in detail in our November, 1915, issue. It (Continued on page 122)
How to Avoid Electric Shocks

By H. WINFIELD SECOR

P EOPLE often receive an electric shock when they least expect it and sometimes the shock may be of sufficient magnitude to prove fatal. It is not unusual to read of live humans often killed in instances of receiving electrical apparatus or to discover that nightly running water, including electrical apparatus and appurtenances, in the home, is so for the reason that if the electrical light socket or switch happens to become defective in its insulation, thus permitting the current to charge the outer metal shell or plate, then when a section of such a shell is grounded, the circuit is completed thru their body to whatever grounded metal object they may touch such as water pipe attachment or standard lamp post.

To the unintimated in electrical matters, it is often a puzzle as to how such an electric circuit is formed, but the answer is simple for the reason that practically all electrical light and power systems are grounded or connected to earth at various points along the feed lines for lighting protection, and also to help to guard users of energy from transformer secondary or low-voltage circuits from receiving a dangerous high voltage shock, should the transformer insulation break down.

Figure 2 shows how a person may be severely shocked or indeed killed by touching a light socket or switch which has a piece of badly mutilated electric cord while standing in a bathtub filled with water. As becomes evident, a person so situated has provided a first-class connection thru the lower limbs due to the water in which the individual stands, and this water has been connected to earth thru the waste pipe connecting the tub to sewer line, and also thru the water pipe supply to the tub which is mechanically connected thereto. An actual case of this nature occurred in Toronto, Canada, about two years ago, when a young man nineteen years of age stood in a bathtub, and so far as is known, he must have touched a frayed electric cord connecting a portable lamp in the bathroom, with the result that he was instantly killed, due to the fact that he had unconsciously provided such an excellent and highly conducting path thru his body. Experts were immediately called in from the London hospitals and a postmortem test revealed the fact that the victim was killed by coming in contact with an ordinary lighting socket wire carrying 118 volts, 25 cycle A. C.; all of which goes to prove that firstly, it is possible for a person to be killed by a 100 to 118 volt shock, and secondly, it would not follow that the badly abraded cord in our apartments or offices as they may spell death to us.

In this connection, it is well to point out another instance. When you have a damp or wet floor of a bathroom or in a bathtub, don't touch any electric switch, wire or fixture. If you must touch an electric switch lamp or wire in such a damp location, take precaution to stand on a piece of thoroughly dry wood or on several thicknesses of dry paper or cloth.

In some cases, a person may unconsciously receive an electric shock by standing on a hot-air heating register commonly found in suburban residences and touching an electric switch lamp or wire under these conditions. An electric current through your body and to the ground through your body. If you happen to touch a grounded pipe system, such as a radiator or water pipe with your hand or in some instances a hot electric knife blade, you will receive a shock more or less severe. See Fig. 3. It might be said that some people, especially electricians, who are used to receiving shocks at 110 volts potential such as electric fans and lights ordinarily operate on, do not mind such a current, but on the other hand, the idea of a shock in the case of the bathtub victim above cited.

As a general thing women are much more sensitive to such an electric shock than men, while animals are very susceptible to such shocks, it having been on record that a horse has often succumbed to a shock of 200 volts.

If you happen to have a short-circuit start a fire in the panel switchboard in your home, office or factory, be careful not to attempt to stamp out the fire with a fire extinguisher or pail of water. There are certain fire extinguishers on the market which are particularly efficacious in quickly and effectively extinguishing electrical short-circuit configurations, and they are of course widely adopted in all power plants and engine rooms as well as in factories. However, some of the first extinguishers project a stream of acid and water on the fire, and if the operator happens to stand on a heating register or is in contact thru his feet or hands with any grounded piping or other metallic system, he is liable to receive a shock, the electric current passing along the stream of acid to the extinguisher and thence thru his body to earth.

In illustration No. 5, we wish to point out a few facts concerning fallen live wires. The first thing to do whether you are electrically educated or not, as past experience has often taught that persons touching a fallen wire, no matter whether you believe it to be only a telephone wire or some other apparently harmless wire carrying a low potential. Persons have been killed in a number of instances by not exercising the proper discretion when brought face to face with this situation. It is not always the case that a fallen live wire will indicate its dangerous condition by making a sputtering noise, but in some cases it will do this, as the writer recently had occasion to note when he nearly stepped on a fallen wire carrying 2,500 volts, alternating current, in which case the wire all but sizzled as he walked thru a group of small sparks to jump thru the insulation which was damped owing to a heavy rain on a particularly moist night, and the wire sizzled similarly to the crackle of auiotric.
How to Avoid Electric Shocks

1. Don't touch water spigot and electric socket at same time
2. Never touch electric wires or fittings when in bath tub
3. Don't touch radiator and electric fan
4. Don't stand on heating register when extinguishing electric fires
5. Leave fallen wires alone; they may be alive
6. Don't use telephone during thunderstorms
7. Keep away from power lines when using electric curling irons
8. Boys: don't throw wires over trolley lines
9. Don't stand on ground and touch live electrical switches
10. Don't stand on ground and touch live circuits or apparatus
11. Don't touch brass nozzle in fighting fires

(See opposite page for full description.)
Electromagnetic Brakes for Aeroplanes

It is a well-known fact that when the aeroplane was first brought out by the Wright Brothers of Dayton, Ohio, one of the greatest troubles they experienced was in making a safe landing. At first wooden skidding arrangements were used, while afterwards heavy rubber pneumatic tires came into vogue to take up the shock when the aeroplane alighted. When an aeroplane lands on a plain or a large grass plot and it comes to rest, the danger is, of course, over. As aerial science is progressing, however, and as aeroplanes are forced to alight sometimes on very narrow platforms, the landing becomes more and more dangerous due to the smaller and smaller landing area which economic conditions make necessary.

It is safe to predict that during the next twenty years our entire mode of life will have been revolutionized. Aeroplanes within ten years from now, particularly during the period of reconstruction after the present war, will become as plentiful as automobiles. The landing problem, therefore, becomes more and more important, and it goes without saying that when aeroplanes alight in a crowded city, they will not have large grass plots on which to land. Naturally the roofs of our tall buildings immediately suggest themselves. Nor is this a new idea. There exists today in Philadelphia a hotel, the “Bellevue Stratford,” which has a landing platform on its roof. But this platform has never been utilized as yet, for the good reason that it has been too dangerous, the landing area being too small.

Up to this time there has not existed a device whereby it was possible to make a landing on a small plot for the reason that when an aeroplane comes out of the sky it cannot stop instantly. Its momentum usually carries it forward as much as 1000 yards. Were the aeroplane to stop abruptly, it would naturally turn either a somersault or otherwise the machine would become wrecked. The same thing only on a smaller scale happens to an express train going at sixty miles an hour when the emergency brakes are set abruptly without the brakes gradually taking up the momentum of the train.

Recently it has been proposed to stop the momentum of aeroplanes by having them land on a wide strip of belting revolving in opposite direction to the oncoming flyer. While this idea is feasible it has never been used in practice, and it becomes obvious that it could not be used except from one direction. For instance, if the aeroplane came on at right angles to the moving belt, it would most likely be overturned. For that reason this device may be considered as impractical. Of course, when the weather is clear and the wind velocity is not great, an expert aviator will not have much trouble in alighting on a comparatively narrow run-way as has been proved right along by seaplanes making successful landings on battleships. At present our Navy has quite a few battleships equipped with narrow run-ways as explained above, but these are useless in a heavy sea, or when a gale is blowing. The reason is that even if the aeroplane should make a successful landing, it would almost surely be tossed into the sea by the combined pitching and rolling motion of the vessel, as well as by the wind trying to blow the aeroplanes into the ocean. Quite a number of accidents have happened in the past due to these causes, and no doubt will happen in the future until some remedy is found.

Mr. H. Gernsback who has given this problem consideration seems to have found an astonishingly simple solution whereby it comes possible to make a landing, on a very small area, no matter what its speed. The present invention on which patents are pending, is described herewith. Mr. Gernsback has also offered his invention to the Navy Department in connection with hydro-aeroplanes alighting on battleships at sea.

Our front cover illustration shows the idea clearly. This shows a future landing station “somewhere in the city of New York” on which a transatlantic aeroplane is just settling; the landing platform in this case is constructed of very heavy glass. Into this glass, which by the way is transparent, are sunk a number of large and powerful electromagnets such as are commonly used for lifting purposes. The idea of the transparent glass is that powerful searchlights can be placed beneath it and the entire glass expanse therefore will stand out sharply from its surroundings. Thus, an aeroplane from a considerable height will see the landing platform readily by night.

The electromagnets in this case would be quite large, say fifty or sixty inches across, each being capable of attracting about 200,000 pounds. These electromag-
ELECTRICAL EXPERIMENTER

June, 1918

In further explanation of Mr. Gernsback’s idea, it will be noted that the aeroplane has two iron-armored, pontoon-like projections instead of the usual wheels, or instead of the usual boats as are used on hydro-aeroplanes. It now becomes apparent that as the aeroplane comes within a few feet of these energized electromagnets, there will ensue a powerful electromagnetic attraction between the electro-

toms and the iron pontoons of the aeroplane. The tendency will be to pull the aeroplane down into contact with the electromagnets, but inasmuch as the flying machine still has considerable momentum, it will not stop at once, but will glide over a number of electromagnets until it finally comes within a few inches of the last row of electromagnets when the maximum tractive effect will be had. The aeroplane will then be pulled down entirely so that pontoons come into actual contact with the huge electromagnets, completely arresting the flight of the airship.

Now it must be understood, and it should be realized that these electromagnets have no effect whatsoever upon the iron pontoons until the latter come within two or three feet of the electromagnets. Elsewhere in this issue we show how close a metallic mass must come to an electromagnet before any appreciable attractive effect is had. From this it will be gathered that this invention does not purport to pull the aeroplane “out of the sky” as some people might think. It does not do anything of the sort. The idea simply is to arrest the motion of the aeroplane while in the act of landing and then hold the machine securely. If these electromagnets were not used, then it undoubtedly would often happen that the aeroplane could not stop quickly enough, and in this case it might slide over the edge of the landing platform down into the streets. Also while making a landing in a gale, such a huge machine which necessarily must have a large wing area becomes a toy of the elements; even if it had completely stopped, the wind might carry it away before the commander would have time to get the engines running at full speed. All this the electromagnetic brakes will prevent. Once the aeroplane has settled, the electromagnets will hold it as securely as if it had been riveted to the platform. Then after the landing has been made, the aeroplane can be readily secured to the platform by guys or ropes, so that the winds or storm will not carry it away; this being only a matter of a few minutes, the power two electromagnets, an enormous tractive effect anywhere from two hundred to four hundred thousand pounds can be readily obtained. Our illustration shows how the invention works out in practice. As soon as the operator who is in control of the electromagnets sees the oncoming aeroplane, he has it in his power to gradually switch, on current into the electromagnets. Thus for instance, the two foremost electromag-

Huge Electro-Magnets of the Type Here Shown Are Proposed in This Article to Arrest the Motion of Aeroplanes. The Illustration at the Left Pictures a 36” Traction Magnet Capable of Lifting a Maximum Weight of 45,000 Lbs. The Casting Shown Weighs 4,800 Lbs. Illustration to the Right Shows a 62” Traction Magnet Lifting a Cast Iron Column Weighing 16,000 Lbs. This Magnet Can Lift a Maximum Dead Weight of 70,000 Lbs.

cans be energized but half or one-quarter if required, so as not to jerk the aeroplane or stop it too soon. In other words a gradual braking action can be had at will of the electrician in charge. If the rolling of the boat and the wind is very strong, he will use more power, or else he can “flash” the electromagnets. By this is meant to overload the electromagnets 50 to 100 per cent. Thus, an electromagnet usually capable of attracting a weight of 100,000 lbs. can be energized by using double the quantity of the current to give a tractive effect of over 200,000 pounds. Naturally this would be only for half a minute or so, as otherwise there would be danger of burning out the windings. However, inasmuch as the aeroplane makes a landing in less than ten seconds the “flashing” of the electromagnets is of no consequence. As soon as the aeroplane has come to rest, the blue-jackets will be ready to lash it fast, and then the current can be switched off.

THE GERMAN WATCH TRICK.

A pet trick that the German soldiers employ is to leave a watch hanging on the wall of their abandoned trenches. Said watch connects by electric wires with a high explosive bomb, which explodes when the watch is removed from the wall.

LADIES! GET A MAGNET!

A magnet will attract a hook and eye which is liable to rust, while it rejects the non-liable ones. So a magnet is a handy tool for the sewing basket.
FLAPPING ELECTRIC FAN RESEMBLES "PUNKAH."

If you have ever visited India or other parts of the Orient, then you will at once recall the "punkah"—the slow-moving, feather bedecked fan, wielded by a husky native at a cost of a few cents a day. Two English inventors, who evidently had sweet memories of a trip to the Orient, have taken out a U. S. patent on just such a "flapping fan," only it is operated continuously, when desired, by the ever obedient genie—electricity.

The employment of rotary fans, say the inventors, whether of the oscillating or other type, as a means of agitating the air for the purpose of ventilation, gives rise to discomfort owing to the fact that the action of the fan produces a continuous draft, usually in one direction only, while, if a rotary fan of the so-called blower type be employed, the resulting introduction of air from outside is or may be objectionable for the reason that such air may have a temperature either too high or too low relatively to that of the air within the ventilated space and may in addition be laden with impurities or micro-organisms which it is difficult to get rid of.

It has, however, been demonstrated by experiment (as recently stated in medical journals) that, contrary to the common supposition, continual renewal of the air within a closed space is not essential to the health or even the comfort of the occupants, altho, for the sake of both health and comfort, it is imperative that the air within the space should be kept in motion. It is, moreover, true that a punkah, as commonly used in hot climates, serves for agitating the air without either creating a continuous draft in one direction or introducing air from outside. But not only are the prime and running costs of a punkah excessively relative to the benefits obtained from its use, but the fact of a punkah being of necessity permanently installed overhead or near the ceiling has the effect of seriously diminishing its efficiency, for the reason that movement is imparted chiefly to the upper strata of the air while the lower strata, which are breathed by the occupants of the apartment, are not directly affected by the agitation set up by the punkah. Who ever thought the punkah covered such a multitude of scientific laws and out-laws!

Something New At Last in Electric Fans—the "Flapper" Fan. It Brings to Mind the Oriental Breeze Producer or "Punkah" As It Is Called. It Is Said to Produce the Most Healthful Circulation of Air Possible. Its Design Is Ideal for Battery Operation.

Hence and howsoever we have with us the gently flapping electric punkah here illustrated, as perfected by Messrs. Term and Boyd of London. The fan actuating mechanism is very simple: in the case of the motor-driven type a cam shaft causes a sliding shaft to work back and forth inside the flexible goose-neck stem shown, thus causing the fan blade to rise and fall alternately. For battery (or 110 volt) systems they have perfected an extremely efficient electro-magnetic mechanism, which is attached to the sliding shaft aforementioned. This design would appear to solve the battery fan problem at last.

ELECTRIC POCKETBOOK ALARM FOILS PICKPOCKET.

A bright electrical genius of New York City, one John P. Williams, has recently taken out a patent on a remarkably electric attachment for pocket-books and such, and intended to be carried on the person, so that when the ever-present pick-pocket attempts to remove the pocket-book or wallet from your hindernest pocket, an electric bell kindly signals the news so that you can then presumably right-about face and nab your man—perhaps.

The electric alarm actuating device is made separate from the pocketbook or wallet and it is provided with a switch on the exterior, so that the owner can open the electric alarm circuit when he wishes to remove the wallet or other papers himself, without starting a riot.

As will be seen, the inventor has gone to considerable pains to make doubly sure that the pickpocket, no matter how well educated he may be in this crafty art, shall not be successful even if he tries to cut away part of the special pocket in which the wallet is placed. To this end he provided a double wall on the protective pocket holding the wallet or pickpocket, this wall containing two oppositely charged metallic plates, or other suitable arrangement of wires or conductors, separated by a layer of insulation and so connected with the battery and bell that should the thief try to pierce the wall of this pocket with any instrument or tool, he will short-circuit the two metallic plates and thus cause the bell to ring.

When the pocketbook or wallet is placed in the protective casings, which is firmly secured in the trouser or coat-pocket by means of a clip provided for the purpose, it is caused to open the alarm circuit by the force of gravity, or in other words by its own weight. The control switch is supposed to be opened while the wallet is being placed in the container, and it slides all the way down in the same, thus causing the alarm contacts to be held normally open by a spring arrangement; then the switch is closed. Should the thief now attempt to remove the wallet, the spring actuated contacts will come together and ring the bell. The inventor suggests two switches, in one of which the bell as well as the battery is placed within the wallet protector case itself, while in the second type the alarm bell and battery are placed in a separate container resembling a watch, and which may be worn in the vest pocket. In this case, the alarm case is connected with the protective watch by means of a fine flexible two-wire conductor.
The Making of an Electrical Man

By FRANK EFFINGER

WHILE America is still preparing to win the war, in other quarters preparations are being followed to provide for after the war requirements. Sad as it is, and as much as we hope 'twill not be so, war's conflicts will now down our numbers of brave, sacrificing soldiers and sailors. The law of war itself says that not as many that went shall return. And a great percentage of the ranks now in France, and preparing to go, are taken from America's industries, not a small number from the field of electrical activity. So, not only is the electrical field greatly vacant now due to the absence of electrical men enlisted in the war services of our government, but it will be more greatly vacant when war's results are counted, and the need for men to fill the industrial places of our soldier and sailor boys will swell the demand.

Moreover, the reconstruction and readjusting periods to follow in war's wake are going to increase the employment of electrical workers beyond even the natural immense requirements. Electricity is yet to do its biggest services to the world after the war. The unlimited are its boundaries now, electricity and men who know its functionary phases and operations will have even wider scope and opportunity for years after peace is declared.

To that end, a new school of engineering located at Milwaukee, Wis., is developing young men to respond to the demand for electrically trained men, developing young men to take the place of those who are not coming back, developing young men to fill the bigger duties our country will thrust upon us after the war is over.

Large quarters in two of Milwaukee's big buildings constitute this school's area, a total of 30,000 square feet. Its capacity is 1,500 students. All branches of electricity are taught and modern materials and appliances. This school has been considered in its idea, methods and equipment, as more of an electric industrial institution, rather than just a school of the orthodox type.

Only the essential theory is taught in text-books and lectures. More stress is placed on the practical instruction, however. The need is for useful men; men who not alone know, but can do. The ability to do things and knowing how things should be done, what to do, etc., is of more vital importance to both the student and the actual field of electricity, than merely a mind of theory, however brilliant, whatever the Alma Mater.

Complete chemical laboratories are contained in the school, where students prepare actual experiments to practical results, followed by full reports made out to the instructor. Also there is an electrical laboratory, where, for example a complete telephone exchange is provided—switchboards, all the intricate parts and even a wired transmission pole, built and practised on by the students. Here is learned by direct contact and operation the technical details of telephony, installation, connecting and all, attended by each student in his practical studies. This complete system is the only feature of its kind in any school. Then there are generators, motors, dynamos, connected and disconnected by students, built, disassembled and rebuilt, and operated as in an electrical plant.

A power plant is provided, fully equipped for students to actually work at and learn by practise and really seeing, as well as reading its laws and solving its problems in class room.

Whoever learned armature winding out of books? Here armature winding is taught by a unique, original method, whereby students learn the requirements of armature winding in every detail by actually
building armatures complete, from the bare iron core to the final form.

A model house is erected in the school, where students in their course of study practises, but has discovered the essential requirements of the electrician and engineer; consequently he is prepared first-hand to teach and conduct his classes to the completely wire a home. They thereby learn that important phase of electrical practise and become thoroly proficient in the art as well as the science.

Thus, in every department of electricity and all its phases, the theory taught is closely supplemented with thorow practise under actual working conditions; the same occupation students will be called upon to follow or supervise when they number themselves among the electricians and electrical engineers of the world. The practical training is given not alone to develop the students to do, but to actual contact and the experience gained, to learn the cause and effect of each detail, every step, and a thorow knowledge of an entire given electrical subject or problem. A man thus educated does not hesitate in answering a query or when put to the test, but responds instantly and emphatically, for he knows the why and the wherefore.

Another feature of practical benefit at this school is the part-time employment of students.

Arrangements are held with leading local industrial and business concerns, who employ students part time. In this way students gain actual business and technical experience, in contact with the world, which aids in their development at school. Furthermore, the students receive pay for the time employed, which adds to their bank accounts or to their school fund, many students thus helping to defray their expenses. This in no way interferes with the students' studies.

This engineering school has an unusual faculty, selected from a standpoint different than customary at most schools. Each and every number of the faculty comes from the industrial life of his vocation. Every teacher has occupied high industrial positions prior to joining the faculty and thus has determined by experience, not only the results of certain electrical and industrial best advantages, consistent with the major needs of the world.

Also, the members of the faculty, being practical men of experience, bear in mind the character development of the students, and this feature, with the fatherly companionship between teachers and student, keeps the students well ordered at school.

THE JOHN FRITZ MEDAL PRESENTATION.

The presentation of the John Fritz Medal to J. Waldo Smith took place in the Engineering Societies Building, New York, April 17.

At this meeting the John Fritz Medal Board of Award presented the John Fritz Medal to J. Waldo Smith for "achievement as engineer in providing the city of New York with a supply of water."

Col. John J. Carty, past president A. I. E. E., presided. The medal was presented by Ambrose Swasey, past president of the American Society of Mechanical Engineers. Other speakers were Nelson P. Lewis, vice-president A. S. C. E., Hon. A. T. Clearwater and J. Waldo Smith.

U. S. HAS GREATEST RADIO IN WORLD.

At the outbreak of war, the United States Navy took over the entire radio service of the country. On account of duplication twenty-eight commercial stations were closed. All those in existence were brought together in a comprehensive system, and other stations erected. The new stations at Pearl Harbor, Hawaii, and Cavitte, Philippine Islands, the most powerful stations in existence, have been completed, as well as the high-power station at San Diego, Cal. The Atlantic Coast stations are in direct communication with Pearl Harbor, and, with this one relay, a message can be flashed from Sayville, Long Island, to the Philippines. By New Year's direct communication had been establisht with Rome. The United States radio system stretches from Alaska in the north to the Panama Canal Zone in the south. In addition to this service, the Navy furnishes radio-operators for the rapidly increasing number of ships. To meet these needs thousands of wireless operators have been enlisted and trained.

At present there are 5,000 at the two principal schools alone, those at Harvard and Mare Island, Cal.
ELECTRO-MAGNETS, poor things, have been frequently adjudged guilty of many short-comings, as well as many, far too many, prodigal but unseemings possibilities since the start of the present world war. All of the misunderstandings and wild dreams of countless patriotic inventors throughout the land seem to be traceable to a lack of definite data as to just what a large electro-

magnet and the steel plate is about 50 tons when in contact. More will be said of this figure anon.

Let us look at the illustration. The largest standard magnet weighs about 8,000 lbs., contains over a ton of copper and requires 15.8 kilowatts of D. C. energy or 72 amperes at 220 volts, D. C. This magnet would not have sufficient capacity to attract a 2-inch cube of steel thru a verti-

ical distance greater than 18 to 20 inches. See Fig. A. Its effect on a larger object would, of course, be somewhat greater. On a steel range boiler (see Fig. B), the magnet might lift the dead weight of the steel thru a distance as great as two feet, not much further. This, of course, assumes that the boiler were stationary with respect to the magnet. If it were moving, as shown in Fig. C, the distance thru which the magnet would attract it would be considerably less. An ordinary range boiler has been selected for comparison here with a torpedo, as most persons have a clearer conception of the former body. From this it is evident that it is practically impossible to arrange booms on a ship, each of the booms being provided with one of these electro-magnets so as to attract enemy torpedoes out of their course, when traveling (Continued on page 139)
A NEW ELECTRIC VACUUM WASHER.

The new electric washing machine here illustrated is said to be a great improvement in the older types. This is a "phantom" view of the new Oscillator Vacuum Washer. Note how the dasher, which is divided into four vacuum compartments, covers the entire surface of all the clothes in the machine. In operation the dasher oscillates up and down with a rocking motion in such a manner that, as one end of the dasher is brought down against the clothes, it forces the water thru them with pressure, while at the same time the other end of the dasher is raised, drawing the water up thru the clothes by suction. Thus the water is forced thru all the clothes twice—once by pressure and once by suction—at every stroke of the dasher, with the result that, literally, many hundreds of gallons of hot water are forced thru every garment in the course of a minute's time.

It is conceded, by those who know, that the vacuum system is the most practical, therefore the machine which most completely utilizes the vacuum principle must be the most efficient type.

In the machine shown this principle has been worked out to the greatest possible degree. With this washer it is not necessary to stop the machine and adjust the clothes. It is impossible for even the smallest piece to become lodged in any part of the tub in such a manner that the dasher does not cover it.

It produces the same satisfactory results whether the tub is filled to its maximum capacity or contains only a few small pieces. The vacuum dasher automatically adjusts itself to the amount of clothes in the machine without attention on the part of the operator.

The new vacuum washer is claimed to wash perfectly the heaviest and most soiled pieces, as well as delicate fabrics and laces, without the slightest wear on material and without danger of tearing. Discs will wear and pegs will tear, regardless of statements to the contrary. Anyone knows that catching a lot of wet clothing on wooden pins or pegs, slushing and jerking them thru the water, first one way and then another, must cause wear and often results in torn clothes. The present machine does not handle the clothes, but forces the hot water and soap thru them washing absolutely clean without wearing or tearing.

Another important feature is the entire absence of valves, springs or other inaccessible parts in the dasher, to hold grease, dirt or acid from the soap. Such accumulations cause corrosion and rust, injuring the clothes. It is unnecessary to raise one side of this machine to drain it. Simply open the drain cock, to which a hose can be attached if desired, and let the water run out. Every part may then be wiped dry with a cloth.

No mechanism whatever is placed on the cover, hence the machine is easy to open and handle. It is operated by a highly efficient electric motor, which connects with any lamp socket or floor plug.

AN ELECTRIC 3-SPEED MIXER FOR THE KITCHEN.

One of the most effective labor-saving machines on the market for the modern kitchen is the new motor-driven three-speed mixer here shown. This machine is electrically operated and the operation is so simple that a child can work it. It takes a minimum amount of electricity to run these machines, it is claimed, the large heavy-duty model requiring but a one horsepower motor. The starting, stopping and changing of speeds is controlled solely by one hand on the machine. It is also possible to stop the mixer without stopping the motor. The bowls of the mixer are rapidly interchangeable, by means of a simple snap spring and can be changed with one hand.

The cut shown is that of the heavy-duty model. This size mixer is for use where heavy and continuous service is required, such as large hotels, restaurants, clubs, institutions, etc. It will mix bread, cake and pastry doughs, beat eggs, whip cream, strain soup, mash vegetables, and crumb bread; and with the extra attachments will grind meat, sharpen tools, buff silver, grind coffee, and many other varied duties.

It has been found by actual test that batches mixed in these machines are greatly improved in quality, and an increase in quantity is also evident. The thoroughness of the mixing makes this possible. Because of the raising and lowering of the bowl, the beater can be worked up and down in the batch, thus insuring that every part of the batch has been well mixed. These machines are also great labor savers, as one machine will do the work of from two to three men.

They have rapidly gained recognition in all fields, and are now being used by the pharmaceutical, drug, paint and polish manufacturers, as well as by preserving and canning houses, where they are used profitably.

NEW TELEPHONE RECEIVER CAP IMPROVES EFFICIENCY.

Here is a new way of boosting the telephone receiver's efficiency via the ear cap, according to the sponsors of the specially designed cap shown.

A scientifically true seat for the membrane "I," prevents the minutest rattling thereof. An inverted trumpet bell, tone concentrating chamber "2," insures of whole, undistorted and most efficient guidance of the sound waves and prevents their deflection and distortion the makers claim.

A radically fluted exterior trumpet bell "3," constitutes a comfortable surface for the ear and permits the impact of each ear-shocking wave to be diverted thru the flutes, which also prevent the sounds from muffling and permits the earpiece to be held in a flat manner firmly to the ear, so as to exclude exterior noises.

Thru the flutes "4," air is freely inhaled and exhaled with each to and fro vibration of the receiver membrane into the outer ear canal, in similar manner, as by the expansion and contraction of the lungs, air is inhaled and exhaled thru the nose.
ELECTRICAL EXPERIMENTER

NEW 800 WATT ELECTRIC PLANT.

Electrical contractors are now in the Farm Lighting Plant business seriously and are finding it necessary to supply their customers with outfits of a better class than the cheap plants sold during the earlier days of the business.

The private lighting plant shown in the illustration has been placed on the market by a Milwaukee concern. It is of the belted type and consists of a generator and switchboard made up in one unit and a storage battery. The various elements of the plant are of well-known standard makes. The best grade instruments and rheostat are used on the switchboard, which also includes a new type of magnetic cut-out which is of an improved design. Glass enclosed fuses are furnished. These plants are made in three standard sizes provided with sixty, ninety, and one hundred and twenty amper-hour batteries, respectively. The generator has a capacity of 800 Watts.

闪亮的新型800瓦特电能装置

电工承包商现在正在从事农用照明设备的业务，并且发现需要向客户提供质量更高的设备。早期出售的便宜设备已经过时了。

图中的私用照明设备由一家密尔沃基公司推出。它是带式类型的，由发电机和开关板组成，并且合成为一个单元。开关板和电池都是标准的，质量可靠。最好的等级的仪器和 rheostat 用于开关板，其中包括一种改进设计的磁性断路器。玻璃封装的保险丝被提供。这些装置有三种规格，分别包含六十、九十和一百二十安培时的电池。发电机的容量为800瓦特。
Burnt-Out Lamp Contest

ELECTRICAL EXPERIMENTER
June, 1918

WE have conducted a good many contests in the Electrical Experimenter in the past, but we are quite certain that our Burnt-Out Lamp Contest has broken every record by far. There seems to be a real enthusiasm on the part of utilizing burn-out lamps, and up to the time of preparing this article, over nine hundred letters have been received, and are still coming in. The oddity of the contest is, that no matter how curious the idea, each has been duplicated, triplicated, and sometimes quadruplicated many as 208 times! Here is the record:

208 Radio Detectors.
80 Florence Flasks, Miscellaneous glassware, Retorts, etc.
28 Geissler Tubes.
21 Magnifying Glasses.
13 Tesla Tubes.
12 Water Rheostats.
12 Emergency Fuses.
11 Batteries.
9 Rain Alarms.

Of this list the electrolytic detectors which rank first have been deemed impractical for actual work, and therefore have not been utilized generally. We cannot make a good electrolytic detector from a standard burn-out 110 volt lamp for the simple reason that the platinum or substitute platinum wires are too thick and at best will only give very poor signals from a powerful station located but a few miles away. The noise in a newspaper office, such a detector is entirely out of question.

Some of the chemical glass ware is being described in this article. The Geissler tube idea has also been used by many a great many times not alone in the Electrical Experimenter, but in other technical magazines. Remember, we wanted original ideas. The same pertains to Tesla tubes, as well as batteries. The magnifying glass idea while new, can hardly be called practical for the simple reason that no one would wish to fill a big bulb with water and use it around the desk for magnifying purposes.

As I mentioned before, all the ideas that came in have been duplicated. The ones which we mention in this article are those received first at our office, or bore post marks, or whatever it was that made the article been mailed first. This we merely did in justice to the various contributors, as among the duplicated articles, all apparently were equally well prepared.

Of course the curious and humorous element was not missing from this contest. Here are a few choice ones: all of these may be termed impractical. There have been suggested the following: wine bottles from 100 watt lamps, chemical fumes, cigar lighters, water heater, clothes sprinklers, and last but not least, all honors go to M. Musselman, of Velsa, N. D., who proposed to fill the bulb with liquid green soap in order to use it for shampoo purposes!!

There were furthermore the following: chemical detectors (using an inverted bent filter paper), targets for rifle practise, filling burn-out bulbs with colored liquids for window attractions. There were quite a good many suggestions of that sort, but the one that has not been seen one of these that would actually work. There were a good many variations on electrolysis apparatus, as was suggested in the original article by Mr. H. Gernsback. There were also several Helmholz resonators, which did not prove useful to us. There were a number of flower vases, fern dishes, candle holders, cigar, and match holders. There were two variable condensers which were suggested for utilizing the lowering liquids in the condenser suggested by Mr. Gernsback. A particular clever one was suggested by Mr. Monte Cohen of New York City. This lamp foil filled with evil smelling liquids in order to have them crash on the domes of "Ham" actors. The idea is to place a push button in front of every man and women in the audience, who if mispleased, simply press a button which would release the bulb onto the unfortunate stage member of the stage male-factors!

There was also a clever miniature volcano as well as a water fountain. Two Hilfs inventors suggested—not such a bad idea,—making megaphones from burnt-out lamp bulbs to be used in connection with telephone receivers. In other words, making horns from the bulbs. There were of course half a dozen inkwells; there were several galvanometers, and even an acetylene gas generator. Mr. E. W. Friedel suggests the filling of the bulb lamp by dripping water on the carbide. There were a number of experimental storage batteries, and we must not forget a clever idea for a lamp suggested by Mr. H. E. Maher of Brooklyn, N. Y. He fills the bulb with the following solution: Chloride of Calcium, 20 parts; salt, 5 parts; water, 85 parts. The bulb is thrown in the center of the fire which is extinguished by the chemicals. Several would-be inventors showed us a device which would weigh a lamp bulb before and after cutting off the tip, the difference in weight of course represents the actual weight of air. While a good idea, as a test for honesty, the experimenters had a sufficiently sensitive scale to detect the slight difference in weight, which of course does exist. There were many suggestions as to batteries which simply consist of utilizing half or three-quarter bulbs in which are placed the usual zinc and carbon elements.

The first prize goes to Elton Baker, 1316 N. 40th St., Omaha, Neb. This is on how to make a static machine by means of a burn-out lamp bulb. Baker's article is reproduced in full herewith.

PRIZE WINNER ($3.00)

A BURNT-OUT LAMP BULB STATIC MACHINE.
By Elton Baker.

The drawings, Fig. 1, show various views of a static machine which I have designed for the "Burnt-Out Lamp Bulb Contest." Also the illustrations show a small 25 watt lamp bulb, much better results can be secured by the use of larger bulbs, as this machine operates on the principle of friction alone. The charges should be collected and stored in the bulb, which is a good sized spark. The jar described by Mr. H. Gernsback in his article on "Burnt-Out Lamp Bulbs" in the April issue will do.

The idea is to make a machine of the shape indicated, made concave on one side to fit the curve of the bulb, covered first with a piece of felt or equally soft material and then with a thin tin burd. To obtain best results the part in contact with the bulb should be covered with a coating of soot, which may be blown or sucked from the back of an old mirror. The collector is made of a similar wood block from which brass tacks protrude so that they are all equidistant from the bulb, and a thin flap is attached to the rubber nearly covering the upper half of the bulb. It is for the purpose of holding the charge on the bulb until it reaches the collector.

Care should be taken that the driving belt turns the bulb towards the collector and also that the tacks on the collector and the leather on the rubber are in metallic connection with their respective brass balls.

The second prize winner ($2.00) is C. M. Cardeaz of Ottumwa, Iowa. His illustration (Fig. 2) shows a lamp made from a bulb which may be used.

The working principle is as follows: The box air, see Fig. 2, rising to the ceiling, causes the air inside the bulb to expand, thereby forcing the salt or acidulated water out of the bulb, and is collected in the cup below, closing the circuit between the two battery wires. These may be connected to a red lamp or bulb, as the owner may desire. The bulb will have nothing to do with the operation of the device, and should be entirely broken by shaking the bulb well while full of solution.

The third prize winner ($1.00) was Mr. Eugene Ruckman, 2209 E. Main St., Ottumwa, Iowa. Nothing further than the illustration to show that he has made this idea fully understandable. When used as a rheostat, slightly acidulated water, or otherwise water to one side of the base, is being added, is used. Thus required resistance can be readily had. When used as a pole tester, the solution (Continued on page 127)
ELECTRICAL EXPERIMENTER

BURNT-OUT LAMP CONTEST.

(See opposite page for descriptive text.)
EVERY time a molecule of any gas gains or loses an electron so as to become electrically charged, it becomes an ion or carrier of electricity. A molecule which loses an electron constitutes a positive ion, and the electron itself may be the negative ion unless it in turn attaches itself to a neutral molecule. When that occurs the neutral molecule becomes negatively charged and it is the negative ion. Hence the smallest negative ion known is a free electron, and the smallest positive ion known is a hydron atom which has lost an electron, the hydrogen atom being the lightest atom which exists.

Electrons may be displaced from molecules by the action of X-rays, ultra-violet light, heat, electric sparks, arcs, flames, emanations from radioactive substances, and by the collision of rapidly moving ions with molecules. Any of these ionizing agents may thus change a nonconducting gas to a conductor and the effect may be proven by placing a charged electroscope in a gas which is under the influence of any one of them, and noticing how quickly it will lose its charge. Different agencies may, however, produce different types of ionization, and a study of these different phenomena leads to a fuller understanding of electricity and matter, and especially the causes of ionization.

X-RAYS.

The X-Rays are one of the best ionizing agents known. In experimenting with ions produced by it, an ionization chamber is generally used which may be of the form shown in Fig. 1. A is the ionization chamber with an aluminum window W thru which the radiation may pass and E and E are electrodes by which the conductivity of the air gas may be measured. The experiments of Prof. Millikan, of Chicago, and others have shown that for the most part the ions seem to be singly charged, which means that when one of these short ether waves strikes a molecule of gas, an electron is displaced. If two or more electrons were displaced at one time the molecule would at once become doubly or multiply charged.

The most noticeable feature of such motion is thereby increased until it is violently shot off from the molecule. Sometimes light is absorbed without producing ionization and in that case the energy of the wave increases the kinetic energy of the molecule without causing the expulsion of an electron. The question as to whether or not a given wave will displace an electron most likely depends on the relative frequencies of the wave and the vibrating electron, and their phase relationship when they meet. A certain amount of harmonic relationship would allow absorption to take place where the lack of it no doubt would cause expulsion. Just what relation this may be is a subject for investigation.

RADIUM EMANATION.

As is well known, the emanations from radioactive substances consist of three general classes, alpha (α) rays or positive particles, beta (β) rays or negative particles and gamma (γ) rays which are very short ether waves. If a gas be ionized by means of beta rays it has been found that single electrons are displaced with very little violence, more as if they were simply set free rather than expelled violently by collision. The same is true of ionization by alpha particles, while the gamma rays act in the opposite way to the other short ether waves.

The beta particle, which is in reality an electron, is so small that it may often pass completely thru a molecule without producing ionization, and it frequently does this when traveling at a high velocity. The alpha particle, which is identified as a positively charged helium atom, may do the same, but on account of its much greater size produces ionization more frequently than the beta particle. Both kinds of rays produce more ions when traveling slow than fast because they then have a less chance of passing thru a molecule without collision, and it is thought that the alpha particle may remove several electrons at one time thus producing multiple charges, but that point is debatable.

The way in which an electron or other small rapidly moving particle may pass completely thru a molecule can be better understood by considering Fig. 2, and remembering that the electron takes up less than one hundred thousand of the volume of any atom and the nucleus or center is probably smaller still. So that as one scientist has said the atom seems to be mostly "betweeness." By the figure it is easily seen that if the separate parts of an atom are actually this small, and if the electrons (e) are rotating at high speed about the nucleus (N) the probability is very high that another small particle traveling in the direction of the arrow (I) will pass completely thru the nucleus without collision. The experiment may be tried of swinging a ball on a string and throwing marbles thru the circle described by the ball, and it will be found that rarely indeed will the ball be hit or even the string.

(Continued on page 139)
Television and the Telephot

By H. Gernsback

(Conclusion)

As we mentioned in the preceding installment of this article, all the telephot schemes which have appeared so far are more or less theoretical. Many of them have not even been the subject of an experimental stage. It seems that while most ideas look more or less practical on paper, it is quite impossible to tell if any of them would actually work in practice. At any rate the various proposed schemes here illustrated form interesting reading for the serious-minded experimenter who is working on this more or less intricate problem. Several of the schemes outlined show a reasonable way towards accomplishing the goal.

Figure 1 shows the telephot of Mr. Sidney Rothschild of New York, on which patents have been issued. Briefly summarized, this invention consists in causing a light controlled composite background to vary the intensity of electrical currents flowing over a wire, and causing these currents to control the intensity of light at the receiving station, this light being caused by an appropriate mechanism to produce a moving luminous spot of varying intensity such a manner as to reproduce the simple image disposed adjacent to the aforesaid background at the transmitting station. The outstanding features are indicated in the illustrations, and the technical details have not been discussed. These can be readily looked up in the patent specifications by anyone sufficiently interested.

At the sending station we have a subject A, whose picture is transmitted thru lens 1, the rays of which fall on the selenium cell 4, after passing thru a belt 3 which is rotated at a high speed. This belt has a number of longitudinal slots disposed crosswise, the belt travelling in the direction indicated by the arrow. A revolving cylinder 9 is provided with a series of slots, each being adapted to register with one of the sections 8 of a further selenium cell. In this manner Mr. Rothschild expects to cut up the various points of the picture and transmit the impulses over the line as shown. At the receiving end, we find a revolving wheel 6 and another rapidly revolving belt 5 which also has longitudinal slots as shown in detail C. By means of a light source shown at 11, which may be an incandescent lamp, the light rays pass thru the revolving wheel 6 and slotted belt 5. The light rays in prises a dark chamber shown in dotted lines, in which is placed a lens 6 which receives the rays issuing from the dark chamber. These rays after being refracted meet a small selenium cell 8, placed behind the prism 6. Screen 1 represents an object (in reality farther removed from the dark chamber than the drawing indicates). The light rays coming from the screen 1 after refraction in the lens 6 which is in front of the dark chamber form upon the endless ribbon 3 a real image reversed and reduced by the screen 1. This ribbon is flat continuous and opaque except at certain perforated points, arranged according to a diagonal line as shown in the detail sketch S. The distance separating the holes displaced the whole of its length, each of the points of perforation has cast into part of the image which is presented to view; thus, the entire picture is transmitted point by point.

At the receiving end we find the sender practically reversed. Here we have another moving ribbon 4 with perforated holes. In the dark chamber 13 we have a source of illumination which may be a kerosene lamp, or an electric lamp or any other kind of a lamp. This lamp throws its rays thru lens 7. Here we have also the electro-magnet 10 which is connected with the selenium cell, and a battery at the sending station. By means of an ingenious shutter arrangement 11, the light rays coming from the lamp 12 are more or less influenced, due to the fact that the electro-magnet is more or less energized by the selenium cell 8 of the sender. In other words when at the sending station, the selenium cell was energized at its maximum, in this case the electro-magnet 10 at the receiving end would be energized as its maximum also, and therefore the shutter would let pass the maximum amount of light. All providing of course that the ribbon 4 was working synchronously with the ribbon 3 at the sender. As the ribbon 4 revolves very rapidly and synchronously with the ribbon at the sender, the picture is thus reproduced point by point and is reconstituted upon the screen as shown at B. Messrs. Anderson have also incorporated into this invention an idea showing how the picture can be transmitted in its actual colors. This is a very ingenious arrangement, but is outside of the scope of this article.

The next telephot, Fig. 3, was imagined...
by Gustav E. Hoglund, of Chicago, Ill. This invention also has been patented, and relates to that class of devices for cutting up and dividing light rays emanating from an image and causing them to act upon a selenium cell capable of changing its electrical resistance under light rays of different intensity. These vibrations are sent over a line and act upon a luminous center at the other end thereof, which may be in the form of a speaking arc and cause a fluctuation in the brilliancy of said arc which will cause light rays to emanate therefrom, said rays being of varying intensity according to the

strength of the current. These rays will follow each other in the same order, and will be of comparatively the same intensity as the light rays emanating from the object. Hence, when the rays from the lamp are projected onto the retina of the eye in rapid succession, they will cause an image to be built up before the eye, which will be composed of the varying light rays of the same strength and in the same order as those emanating from the original image.

The device shown in Fig. 3 has a receiver and a sender; each of the instruments comprises a selenium cell 5, positioned in front of which is the enlarging lens 4 and the reducing lens 3. Between these lenses is a double revolving shutter composed of discs 7 and 8. These are also shown in a detail sketch. Disc 7 has a series of square perforations 10, while disc 8 has a series of slots 11. It will be seen that as these discs revolve in opposite directions, each point of the picture is cut up successively and allowed to pass thru the optical lens system. Each of the receiving instruments also comprises a lamp 1 and enlarging lenses 2. Between these lenses a ground glass plate is placed, upon which the final picture appears. Both receiving and sending instruments are connected by electrical lines as shown. The oppositely revolving discs are ordinarily actuated by means of the synchronous motor 10.

An interesting part of this invention is that these revolving shutters can be corrected if they do not run synchronously by means of handle 9. It becomes apparent that the two shutters must be brought into proper relation to one another; this can be easily determined when such a relation is found by observing the image from the receiving instrument. If the shutters are not in proper relation, the image will be nothing more than a blur, and before it can be distinctly seen, the shutters will have to be in appropriate relation to bring the openings into the desired position. The inventor therefore provides

handles 9 which extend from the shutters and by turning these handles, the shutters can be revolved until they are brought into proper relation with one another, the operation determining when such position has been reached by observing the completeness of the image reproduced by the receiving instrument. Once the shutters are in proper relation with one another, the motors are then supposed to operate them synchronously. By studying the illustration, it will be noted that the lamps 6 are varied into their proper luminosity due to the selenium cells 5 receiving more or less light.

While this scheme looks very feasible on paper, we are afraid that the lamps 6 will not respond instantaneously to the current variations in the selenium cells 5, and at best the picture would seem to us to be formed rather blurred.

The next telephopt which has also been patented in several countries is shown in Fig. 4. The inventor of this telephopt is Boris Rosing of Petrograd, Russia. In order to eliminate the synchronous motor arrangements which have been the failure of almost all telephopt schemes, Mr. Rosing does away entirely with them, substituting therefore a system comprising two oscillographs with movable reflecting surfaces. This will be apparent further on.

The optical system at the transmitting station comprises two polyhedral rotary mirrors, 1 and 2, the axis of rotation of which are at right angles to each other. They are driven at such speeds that the angular velocity of one of the mirrors is several times greater than the other; and an objective or lens 5, the focal plane of which coincides with the plane of the screen 6 and the photo-electric receiver 7. The objective 5 is arranged in such a manner that rays emitted from any point of the field of vision arrive in the photo-electric receiver only after successive reflections by the two mirrors. When the mirrors 1 and 2 are rotated, the end 8 of the optical axis thus deflected traverses the field of the picture in a zig-zag path, so that from every portion thereof light is transmitted in a certain determinate order thru the opening of the screen 6 upon the photo-electric receiver 7. Permanent electric magnets carried by the mirrors 1 and 2 and stationary bobbins 3 together form small generators producing in the corresponding bobbins pulsating currents, the periodicity of which per revolution of the mirror corresponds to the number of reflecting surfaces thereof. The currents which are produced in the conductors 9, 10, 11, 12 and transmitted thru the receiving station are proportional to the components in the directions of the axes of a corresponding system of coordinates of angular movements which the optical axis 8 executes in the field of view.

At the receiving side we find two oscillographs provided with mirrors 13 and 14. The axes of both are arranged to correspond to the axes of rotation of the mirrors 1 and 2. Lens 16 directs the rays proceeding from the luminous signaling point 15 on to the small mirror 13. There will therefore be imparted to the deflected optical axis 17 at the receiving station, the same movements in space which the deflected optical axis 8 at the sending station executes at the transmitting station. It goes without saying that the moving parts of the oscillographs naturally have much less inertia than do the revolving sets.

A different idea in which Rosing's invention is shown in insert C, Fig. 4. Here instead of using oscillographs, the inventor

(Continued on page 124)
The Dynatron—a New Vacuum Tube

The dynatron belongs to the kenotron family of high vacuum, hot cathode devices which the research engineers of the General Electric Company have developed, and was described in a paper read before The Institute of Radio Engineers by Dr. Albert W. Hull. Two members of this family, the kenotron rectifier and the pliotron, have already been described in this journal. The fundamental characteristic of kenotrons is that their operation does not depend in any way upon the presence of gas.

In construction, the dynatron resembles the kenotron rectifier and the pliotron. In principle and operation, however, the three are fundamentally different. Each utilizes a single important principle of vacuum conduction. The kenotron rectifier utilizes the uni-directional property of the current between a hot and cold electrode in vacuum. The pliotron utilizes the space charge property of this current, which allows the current to be controlled by the electrostatic effect of a grid. The dynatron utilizes the secondary emission of electrons by a plate upon which the primary electrons fall. It is, as its name indicates, a generator of electric power, and feeds energy into any circuit to which it is connected. It is like a series generator, in that its voltage is proportional to the current thru it, but it is entirely free from hysteresis and lag that are inherent in generators and in all devices which depend upon gaseous ionization.

The dynatron consists essentially of an evacuated tube containing a filament, a perforated anode and a third electrode called the plate. The essential construction is shown in Fig. 1. The plate must be situated near the anode, in such a position that some of the electrons, set in motion by the anode voltage, will fall upon it. A battery is provided for maintaining the filament at incandescence and for maintaining the anode at a constant positive potential of 100 volts or more, with respect to the filament. This voltage is not varied during operation, and the anode plays no part in the operation of the tube, except to set in motion a stream of primary electrons, and to carry away the secondary electrons from the plate that is to supply the power.

The illustration, Fig. 2, shows the construction of one of the practical types of dynatron that have been developed. The plate, as will be observed, has been bent into the form of a cylinder, in order to utilize more fully the electron emission from the filament, and the anode has been provided with a large number of holes, instead of one. This is accomplished by using a perforated cylinder, a spiral of stout wire, or a network of fine tungsten wire. The filament is a spiral of tungsten wire. The filament may be further provided with a heavy insulated wire along its axis or surrounded by an insulated spiral grid, making a "four member" tube, which is called a pliodynatron. The characteristics of the pliodynatron are discussed later on.

Electrons from the filament F (Figure 1) are set in motion by the electric field between F and the anode A. Some of them pass first the holes in the anode and fall upon the plate P. If P is at a low potential with respect to the filament, these electrons will enter the plate and form a current of negative electricity in the external circuit. If the potential of P is raised, the velocity with which the electrons strike it will increase, and when this velocity becomes great enough, they will, by their impact, cause the emission of secondary electrons from the plate. These secondary electrons will be attracted to the more positive anode A. The net current of electrons, received by the plate, is the difference between the number of primary electrons that strike and enter it and the number of secondary electrons which leave it. The number of primary electrons depends on the temperature of the filament and is practically independent of the voltage of the plate. The number of secondary electrons, however, increases rapidly with the voltage difference between plate and filament, and may become very much larger than the number of primary electrons; that is, each primary electron may produce several secondary electrons, as many as twenty in some cases.

If the dynatron be left open-circuited, as in Figure 1, it is unstable. The same instability occurs if the circuit of Figure 1, instead of being left open, is closed thru too high a resistance, so that the rate at which the plate receives electrons is greater than the rate at which these electrons can flow away thru the resistance. (Continued on page 122)
Major-General George O. Squier

Major-General GEORGE OWEN SQUIER, well known to all electrical and radio men for his important achievements in telephony and telegraphy, is at the head of the U. S. Signal Corps, one of the most important branches of our army. General Squier has a large number of problems to contend with in his capacity, for besides his multitudinous duties in building up an efficient Signal Corps arm of the Service, equal numerically to our entire army before declaration of war, he has had charge of the aviation work of the Government.

Major-General Squier was born in Dryden, Mich., March 21, 1865, in the old homestead which he still owns, and which was settled by his grandfather in 1835. In 1883 he was chosen for West Point, and in 1887 graduated seventh in a class of 65. Appointed second lieutenant in the third Artillery at Fort McHenry, Baltimore, on June 12, 1887, he put in all his spare time studying physics at Johns Hopkins University under such leaders as Rowland, Kresnell and Newcomb. There he laid the basis of his scientific knowledge, being made a fellow of the University during the years 1902, 1903, and 1904, and receiving his Ph.D. degree in 1903.

He announced before the American Institute of Electrical Engineers, in 1897, a new method of rapid telegraphy, based on the use of the alternating current with the polarizing photo-chronograph. Three years later he announced to the same society the adaptation of these principles to cable telegraphy, using the sine wave "e. m. f.'s" as worked out in experiments begun the year before with Dr. C. Crehore.

In the meantime his military career claimed him, especially during the rush of the Spanish War. In 1900 he took the cable steamer Bunsen from New York thru Suez to the Philippines, where he laid the inter-island cable still in use. During this time he rose thru various ranks till he was commissioned a Major, 2, 1903.

In 1907, as Chief of Staff to General Allen, of the Signal Corps, he was entrusted with drawing up the first specifications for a military radio telephone by any government. On September 12, of the next year, when in charge of the first tests at Fort Myer, he made the first ascent as a passenger in an airplane ever made. That December he showed his faith in the future of his cable transmission invention, which later led to its adoption. It is estimated that this doubled the capacity of the cables.

It was in May, 1916, with the war two years old and the vital importance of aviation fully demonstrated, that he was recalled to America by President Wilson to reorganize the Air Service. On the 14th of the following February he was appointed Chief Signal Officer in charge of aviation and the Signal Corps, with the rank of Brigadier General, which was increased to Major General on October 6, 1917.

During the brief eight months since he has been in charge, the Air Service has jumped from a strength of 2,000 to an authorized strength of 135,000; its appropriations have increased from about a million dollars in five years to $700,000,000 granted in one, and a billion asked in the next; its planes and aviators have increased from a hundred to thousands. The Signal Corps itself has had to meet the needs of an army eight times that of a year ago.

General Squier is a Fellow of the Physical Society of London; a member of the Royal Institution of Great Britain; the American Mathematical Society; the Franklin Institute; the American Association for the Advancement of Science; the American Physical Society; the American Geographical Society; the American Institute of Electrical Engineers; the Institute of Radio Engineers, and other scientific and professional bodies. He was awarded the John Scott Legacy Medal in 1896 by the city of Philadelphia for the polarizing photo-chronograph, and in 1912 the Elliott Cresson gold medal, the highest honor of the Franklin Institute, for his work in multiplex telegraphy on "wired wireless," by which half a dozen wireless messages run outside of, but are guided by a single wire. He has also issued inventions in the use of trees as antennas in wireless telegraphy; the electro-chemical effects of magnetization, and the absorption of electro-magnetic waves by living vegetable organisms.

Electricity plays a tremendous part in the preparations being made for the reception of American troops in France. From the refrigeration of food to the lighting of first line trenches, electricity is employed at almost every step.

SOCIETY GIRLS WILL INSTRUCT DRAFTED MEN IN RADIO.

The Women's Radio Corps of America is training at New York headquarters a corps of young ladies, most of whom are prominent in New York social circles. The members of the corps will later instruct classes of drafted men in buzzer and radio signaling. The photo shows Sergt. Georgiana B. Davids (left) and Sergt. Elise Owen, who are in charge of the students. This idea seems a capital one to our minds—instead of attempting to place women radio operators in hazardous war positions, why not train them to teach? Here's a big field, surely, one that is bound to expand as more and more of the flying cadets are marshalled in the training centers. And thousands, and even tens of thousands of these future flyers will have to be taught radio operating in the next year or so. In this way the women will find a most satisfying way of knowing and feeling that they are actually doing "their bit" for Uncle Sam.
A "Fountain Pen" Radio Receiving Set

While not an entirely new innovation the "Fountain Pen" Radio Receiving Set has laid the invariable drawbacks of all new devices, as well as lack of practical use. But now a new application has been given to it that with so many "spies" at large, it has become a necessity to detect many of these enemy aliens, who undoubtedly are using some wireless apparatus to communicate information to Germany, or between themselves.

To Dr. Lee deForest must be given the credit for developing a receiver which is only slightly larger than an ordinary "Fountain Pen." With it, a secret service man has but to walk in the vicinity where a "spy" has been suspected, with the chance that he may locate the informer at his instrument.

With this "fountain pen" Radio receiver it has been possible to hear stations eight to ten miles away, with little difficulty and only a small aerial. In the sectional view shown herewith may be seen how it is hooked up. This sensitive receiver depends entirely upon the Audion for its efficiency, and it is only the extremely sensitive detector that has made possible a truly practical receiver of this small type.

It has been found that by using what is known as a "soft" Audion a fair degree of sensitivity is achieved with a battery of only four volts whereas a standard Audion requires a potential many times that amount.

The tuning of the set is accomplished by means of a small coil, wound with No. 40 magnet wire. Taps are taken off from the coil and led to a number of points over which slides a contact mounted on the movable cap at the end of the receiver. By moving the cap one way or another the wave-length is altered to conform with the incoming wave. The tuning coil answers satisfactorily for short wave-lengths, and the Audion is connected directly to it, having an untuned secondary. The battery is placed in the middle of the receiver and at the end is placed the telephone receiver consisting of a special magnet, bobbin, diaphragm and earpiece. The antenna and ground connections are instantly made by a special double contact plug.

To operate the instrument the person using it has a metal plate attached to the heel of one shoe to which is attached the ground wire. He is leading to the set the wire being past through the trouser leg so as not to be seen. The wire to the antenna is run down through the same coil and into a hollow cane which may contain a spiral aerial or a similar arrangement.

Standing against an iron fixture which connects with the ground the operator places the metal electrode on the heel in contact with the same. The cane containing the antenna is held over the shoulder or in any position not likely to cause attraction. The earpiece is placed against the ear and the other end adjusted till the signals are heard loudest.

The transformer is about the most efficient piece of electrical apparatus, it having an efficiency of about 98%.

A specially built and cleverly contrived generator designed to give an exact reproduction of radio signals has been perfected and put into use at the Dunwoody Industrial Institute, in Minneapolis. This high frequency generator is used instead of a buzzer for producing the practise signals in the "phones." The generator has 96 poles, the rotor, which is the field, is revolved at a speed sufficient to give a clear musical note of about 600 cycles. The frequency as well as the strength of the signals can be easily varied. As a result of this arrangement the student gets practise in receiving an exact imitation of the modern radio signals, such as are sent out by undamped wave generators and quenched spark sets. The head 'phones' are connected directly to the primary coils of the Audion thru the transmitting keys. The generator is driven by a one-sixth horse-power electric motor.

This Special Yet Simple Form of High Frequency Generator is Used at A Leading Radio School to Supply the Proper Tone of 'Phone Current.
NEW RADIO KEY HAS BALL BEARING CONTACTS.

An interesting and highly efficient radio key recently perfected by a New York radio engineer, Mr. L. G. Facent, is illustrated in the accompanying photo. It is built in a precisional manner throughout, having extra long, deep-seated pivot bearings for the key lever proper, which ensure long service and accurate functioning of the complete instrument. The key is mounted on a lakelite base, giving entire freedom from dampness leakage, etc. cetera.

The contacts are extra large and made of silver. All radio men know how difficult it is to properly align key contacts, especially when badly burned, even after they have been carefully filed clean and flat again. Ingenuity on the part of the designer of the present key has solved this problem in an admirable manner. He mounts the upper contact on the key lever in the usual way; the lower contact is mounted on a ball and socket joint. With this means provided it is the work of but a moment to loosen the lock nut clamping the ball-supported bottom contact and to align it accurately with the top contact. The key has been approved by the Navy Department.

RADIO OPERATING IN ALASKA.

By Howard S. Pyle,

Electrician-Radio, U. S. N.

It may be of interest to the readers of the ELECTRICAL EXPERIMENTER to know what we of the Pacific Coast have to combat in the way of mountain ranges and other natural causes which contribute in making a commercial operator's life in Alaska, one of constant speculation as to whether his business is going to get thru or will be hung up somewhere because a station can’t “get thru.”

I recently completed a trip on the S. S. Rush of Everett, Wash., from Everett to Heringooy, Alaska, in the Bering Sea, by way of what is known as the inside passage, that is: hugging the coast of British Columbia all the way north, between the main land and numerous islands.

My kit included the new Kilbourne and Clark two kilowatt, 500 cycle mercury arc quenched transmitters and at that time was probably the most efficient type of marine equipment in use on this coast. The receiver was of the ordinary, inductively tuned type with silicon-arsenic detector, but as my crystals were of a very poor quality, I had no opportunity to hang up any receiving records. My antenna also was mountains that tower way above the vessel on either side. Here I was practically in a “dead hole,” not hearing a signal during the time of passing thru except from the S. S. Zepora, WPQ, who was just ahead of us in plain sight. After leaving the Canadian coast and entering Alaskan waters we were coming very close to Ketchikan, Alaska, (KBP) but owing to intervening mountain ranges could hear his signals only about fifty miles on either side, although there is a very efficient and powerful installation there. A vessel as close as we were has difficulty in working with him, but at a distance he is easily readable clearing business with Astoria, Oregon, every day. We progress up the Alaskan coast and when attempting to work Sitka, (NBP) found it almost impossible, except when we were all most opposite him, being on the east side of the island. This was due to mountainous country intervening between.

After leaving Hoonah, Alaska, we struck straight across for Corvallis and Kodiak and had no trouble working either of them all the way across. When we entered the water between Kodiak Island and the mainland, I lost Kodiak’s signals (NPS) altogether, until exactly opposite him when I handled a little business direct, losing him again shortly afterward. I then tried to get in touch with Dutch Harboor (NPR), but could hear nothing of him until within one hundred miles, when he came in strong. I kept in touch with him for about two hundred miles of travel in the Bering Sea and then lost him and picked up St. Paul Island, (NPO). I kept in communication with him all the way to Port Moller, where we anchored a few day on account of the ice. When we finally proceeded into Herendeen Bay in the middle of everyone. Could hear NPR, NPO, S. S. Winber, WND, at Chignik and S. S. Norwood, WSG, at King Cove very good at Port Moller, but five miles into the bay every thing faded out entirely. We lay in the bay for two weeks, during which time I was compelled to relay everything thru KWR at Port Moller, even tho the S. S. Winber was only fifty miles due south and with Audion equipment could not hear me. I could hear nothing of her either, in spite of her using high power or full two kilowatts.

Do our Radio brothers of the east coast have these troubles?

June, 1918

CODE BUZZER TRICKS.

By E. Duskis

Of late there have come out on the market some wireless practise buzzers which are very good in every way for learning and practising the code. The general form of these buzzers consists of an arrangement as shown in the diagram, Fig. 1. This is also the standard hook-up given with these buzzers.

Of course the above arrangement is satisfactory, but there may be too loud a note produced in the telephone receivers; in fact, so loud as to do harm to one's ear-drums. With the end in view of reducing the intensity of the signals in the telephone receivers, to signals of equal intensity as usually received in a wireless station, the following methods are proposed. They work well, as they have all been tried out.

The first method of connecting the buzzer in the manner shown in Fig. 1-A has the advantage of reducing the intensity of the signals just to the strength of the wireless signals.

The second method gives equally good results to the preceding method, but uses a small fixed condenser in series with the phones connected as shown. This condenser can be the standard condenser that is usually shunted across the phones in wireless circuits. The advantage of this method is that, while the key is open, no current flows in any part of the circuit, but while it has this advantage it must be seen (when comparing it with method No. 1) that it necessitates the use of a condenser, which costs more than a switch.

When using the hook-up given in method number one, it is imperative that the connections be made as per diagram given in Fig. 1-A, for if the connections are made as shown here in diagram, No. 3, there will be a click, followed by the high pitch note, in the telephone receivers. It is to be noted in connection with diagram No. 3, however, that, while it possesses the disadvantage of giving a click and then the high pitch, it is an advantage, because under these conditions it provides a fine means for learning the Morse code, and
About Learning the Code

By ALAN C. ROCKWOOD

In the January issue of the Electrical Experimenter, Thomas Reed proposed a new scheme of mnemonics for learning the Continental Code (page 615). Several years ago I attempted to learn the code by a similar system, but I never succeeded until I tried another plan. Therefore I shall tell my experiences with plan and the reasons it was unsuccessful as an aid to memory.

In learning to receive by ear the ultimate object is to be able to write down the letter as soon as the sound is heard. If this proficiency is attained the reception of a letter consists of three steps:

1. The operator hears the signal.
2. The operator thinks of the letter represented by association of ideas.
3. The operator writes down the letter.

In practise this becomes so natural that there are only two steps: the operator writes down the letter without consciously thinking.

In contrast with this process there is the method by which most people try to learn the code, by calling off the dots and dashes for each letter. In this method there are four steps:

1. The operator hears the signal, (say "ah").
2. The operator thinks of the sound as heard in the terms of dots and dashes. ("dot-dash").
3. The operator associates the combination of dots and dashes with the letter (in this case "a").
4. He writes down the letter.

The second step takes the longest time of all because the operator has to change the sound to a visual picture of the dots and dashes. In the third step he must change from the visual picture of the dots and dashes to the picture of the letter. As this takes times and must be dropped as soon as the operator is proficient, it would be much better to learn the code in some manner in which it would not be necessary to waste the time in making the transition from one process of connecting the sound with the letter to another. In my view, therefore, the most perfect system of mnemonics would be one whereby each student learned each letter by the exact sound it made in the receivers.

Upon examining the proposed plan it is seen that it does not conform to this standard, but is open to the same objection as the process of memorizing the letters by dots and dashes. It merely substitutes for the second and third steps of the second plan, as outlined in the preceding paragraph, the linking of the sound with a "Fonetic Catchword" and the linking of this with the desired letter. This is simpler because the catchword is aural, the same as the signal received, but it does not remove the entire difficulty.

The extra step is there which must be learned and unlearned. It is desirable to have a system in which it will be necessary to unlearn as little as possible. Another objection which I discovered when I tried to learn the alphabet by this method is that it is hard to keep the catchwords separate and linked with the letters they belonged with. For instance, the catchword for J was Je-ra-a-len and for L was Lo-ben-gua. Both of these were of the same number of syllables and I found, when receiving, that I would often think of them as Je-ra-a-sam and Lo-ben-gua. Therefore, at those times I would get — as L, and — as J. I believe that Mr. Reed's plan would be open to the same difficulty of confusion of characters and that some other method should be considered.

In considering the plan to be devised it is necessary to consider what we are striving for. The perfect plan would be the one that makes the easiest transition from one stage to another or in which there is no such transition. Under this each student, from the first, would know each letter by the sounds in the receiver. This is to practise over the code between lessons to make sure of himself. As it is not possible to imitate the radio signals exactly it becomes necessary either to repeat the words dot and dash for each letter, to use catchwords, or to approximate the sounds of the letters. This last scheme is the best because by its use the change from the carrying thru of each of the three steps in detail to the immediate perception of the letter is gradual. This fulfills the requirements because nothing need be forgotten. The only question is how to approximate the sound best.

Mr. Reed says that for "V" the receiver says "siss-a-siss-siss." This is an approach to it, but this cannot be used at the rate of even 20 letters per minute. Try it! The plan that was used successfully in the Iowa City High School Radio Club last year was as follows:

a. For a dash use the syllable dah (a as in arm).

b. For an initial dot use tuh (u as in up).

c. For a dot not initial use dhu (u as in up).

By remembering that a dash is equal to three dots in length, that the space between parts of letter is equal to one dot and that the space between letters is equal to three dots the cadence is gained. Thus A is tri-d a h, B is dah-duh-duh-duh. C is d a h-duh-d a h-duh, and so on.

I know personally of over a dozen people who have learned the code as I have suggested and have only heard of one who learned by catchwords—and he learned it only for visual signaling. If you have had any experience with either method or know of any better system write it in to the Editor and he will pay you for it if publish.

Don't miss the article on "Harmonics—Part II" by Prof. E. E. Austin, in the next issue of the Electrical Experimenter. It explains the analysis of irregular shaped alternating curves.
The Design and Use of the Wave-Meter

PART III

By MORTON W. STERNS

(Continued from the April Issue)

For most of the data and description of the Kolster Decimeter the author acknowledges indebtedness to the Bureau of Standards Bulletin No. 235 on the same subject. Due to the complex theory in back of the design of the condenser the reader must pardon some higher mathematics necessary in order to properly explain the design of the condenser.

The shape of the moving plate of the ordinary variable condenser in common use is such that for equal angular displacements of these surfaces from the position of minimum capacity to that of maximum capacity, an approximately straight line variation of capacity is obtained as in Fig. 1. It is evident from the figure that for any given displacement ΔC of capacity will not be equal all over the scale.

In order that the instrument may be direct reading as to decrements the capacity variation in per cent must be constant over the entire range from maximum to minimum ΔC, i.e., b must be a constant.

By a mathematical solution which the interested reader can find in the original paper the author points out that the capacity of the variable condenser must vary in accordance with the law of geometrical progression, and it is easy to formulate the equation between the value of capacity and the position of the moving plates. Since the curve of capacity must obey the law of geometric progression, we have in Fig. 2:

\[ x = 0 \text{ let } C_0 = a K^0 = a \]
\[ x = 1 \quad C_0 = a K^1 \]
\[ x = 2 \quad C_0 = a K^2 \]
\[ x = 3 \quad C_0 = a K^3 \]
\[ x = n \quad C_0 = a K^n \]

In general \( C = a K^\theta \) ......... (9)

A simpler deduction is as follows: in accordance with differential calculus, the following fundamental requirement of the condenser may be written:

\[ \frac{dC}{C} = -\frac{dx}{x} \quad \text{(10)} \]

\[ \log C = nx + h \]
\[ C = K^x \quad \text{(11)} \]

Since this is equivalent to equation (9) we may say for a rotary variable condenser where \( \theta \) is the displacement angle in degrees.

We know, neglecting edge effects, that the capacity of a condenser is directly proportional to the active area of the movable plates or

\[ A = b K \]

where

\[ A = \text{active area of moving plates} \]
\[ b = \text{constants deduced later} \]
\[ \theta = \text{angular displacement} \]
\[ E = \text{base of napierian logarithms} = 2.71828 \]

By analogy with equation (10)

\[ dA = -m d\theta \]
\[ A = b K \]

(12) or \( dA = bm E^m d\theta \)

Eq. (13) \( A = \int bm E^m d\theta = bm E^m \log E = bm \]

Referring to Fig. 3.

\[ (14) \quad dA = \frac{1}{2} (r^2 - r^2) d\theta \]

\[ r \quad \text{being distance from center 0 to enveloping curve of the plate, or radius vector} \]
\[ r \quad \text{being radius of small circular space (inactive), occupied by the separating washers between plates} \]

From (12) and (14):

\[ \frac{1}{2} r^2 - \frac{1}{2} r^2 = bm E^m \]

and

\[ r = \sqrt{2 bm E^m + r^2} \quad \text{(15)} \]

where \( b \) and \( m \) are constants which determine the maximum and minimum value of capacity.

Since equations (10) and (11) are identical we may write

\[ K = E^m \]
\[ x = \log K = m \theta \]

\[ m = \frac{x \log K}{\theta} \quad \text{(16)} \]

where \( K \) is the ratio of maximum to minimum capacity.

In the first article it was shown that 0 to 1 is a good ratio of maximum to minimum capacity, so substituting in (16), assuming \( x = 1 \) when \( \theta = 180 \).

\[ \theta = \frac{180}{180} \]

\[ \log K \]

\[ \frac{180}{180} \]

\[ .043 \]

\[ \text{if we assume some value of area in square inches for a movable plate and substitute} \]

\[ A = \int (E^x - 1) \]

Assume a value of \( r \) the radius of the washers and calculate \( \rho \) for various angles \( \theta \) to give the shape of the curve which will be a logarithmic spiral. This is the case in Fig. 4.

Now knowing the capacity wanted and the area of the plates and thickness of spacing washers we determine definitely the number of moving plates and since it is more convenient to make the stationary plates semi-circular it is merely a mechanical trick to assemble our condenser.

In the actual Kolster decimeter the capacity of the variable condenser is slightly lower (Continued on page 140)
TO PREVENT BURNING OUT AUDION FILAMENTS.

Audion bulbs are being burned out daily just because some inexperienced or even experienced operator raises the current up to what he visibly thinks is a safe point and then (if, out) goes said bulb and also your pocketbook gives a long squeal.

In the accompanying drawing I show how this can be eliminated, merely by using some means of warning. Build a small relay as shown, then adjust the spring so as it will only close the bell circuit when the danger point is about to be reached. Of course Audion circuits provided with ammeters are quite safe in this respect, but even with this precaution I have seen bulbs burned out.

I think the alarm shown in the diagram will save many a bulb; when the danger point is about to be reached, it closes the circuit and rings the bell, thus warning the operator who is adjusting the filament battery.

A DETECTOR HINT.

I have a detector which has two cups placed opposite each other and made adjustable by turning a knob. I use galena, with a light phosphor bronze wire contact. I found that by attaching a battery and rheostat in series with the cups, that the signals were greatly increased in intensity and the range of my set was greater by far. I picked up stations impossible to hear without the battery attached. Too much current will fuse the crystal. The best voltage will be determined by experiment.

Contributed by P. B. KINGSLEY.

FILING GLASS.

A file is generally employed only on metals, and glass is about the last substance that one would expect to be capable of being filed. Glass can be shaped with a file, in cases where the usual blowpipe methods are not applicable, if the file is kept wet with turpentine. A still better lubricant is made by steeping camphor in turpentine and using the resulting solution. A simple alternative method, not quite so satisfactory as the above, is to immerse the glass in water while the filing proceeds. A piece of sheet glass can be cut with a pair of scissors under water.

Contributed by H. J. GRAY.

HIGH TENSION BINDING POSTS.

Old blown out cartridge fuses can be used very economically as a high tension binding post for step up transformers, spark coils, etc., requiring a binding post that will not "leak." Take one of the old fuse (about 60 amperes) and cut it in two with a hack saw. A hole is drilled thru the metal cap large enough to take a bolt that will hold a binding post from an old battery or any good binding post. The bolt is long enough to reach thru the fuse and fasten on the top of the instrument. The connection is made on the nut under the top of the cover.

Contributed by LOUIS LOOTENS.

A SIMPLE BALL-JOINT DETECTOR.

Here is a detector stand for the amateur who wishes one for quick adjustment and one that holds its adjustment when once set. The ball and rod may be taken iron or brass. Here's a Good Method of Simplifying the Tuning of a Radio Condomenser and inductance. The Shaft is Belted or Geared to the Inductor. The Condenser Shaft is Belted or Geared to the Inductance Switch Handle.

SIMPPLYFING THE TUNING OPERATION.

The sketch herewith shows a new wrinkle for correcting loss of time in making changes of wave length as far as the secondary is concerned. It is easily seen that both condenser and inductance can be changed without the use of both hands, thereby leaving the other hand free to be used in changing primary adjustments, etc.

Building an Electric Piano Player

By CHARLES HORTON, Consulting Engineer

(CONCLUDED)

SINCE there must be eighty-eight contacts, a simple method had to be developed for forming them. They are, in this model, formed of cotton-covered magnet wires of, say, No. 12 B. & S. gage, each one being fastened under a screw in the back of the board L, then led forward over the tracker bar and back again where it is connected to its magnet wire. This is clearly shown in Fig. 6 and Fig. 5. The contact wires are inserted one by one over the tracker bar and finally all clamped tight by means of the strips 23 and 24. When this is finished several coats of thin white shellac are applied to them, and when the shellac is set hard a file is used to lave the copper wires at the highest point on the tracker bar. This is the same method used formerly in making adjustable tuning coils and is very satisfactory for this purpose. Careful examination of the drawing will be essential to a proper understanding of the arrangement, which is really very much simpler than it looks at first sight.

A wiring diagram is given in Fig. 7. This shows the connections for one contact and one magnet, and, of course, all are similar. The parts are given the same letters and numbers as in the other views. At the point N the return wires from all return of the striker. Detail 3 is one of the seven boards forming the bottom of the striker box and has twelve holes for the twelve bobbins for one octave and other holes for the retaining bolts. These retaining bolts are one-quarter inch stove bolts and should be of iron or mild steel, as it will be seen on examination that they not only hold the magnets in place, but also complete the magnet circuits of the magnets, thus making them stronger in action. Detail 11 and 12 are iron or mild steel pieces used in place of washers for retaining the third and fourth row of magnets; 8, 5, 10, 17 and 18 need no further explanation; 14 and 15 are tubes of brass slip on between the striker cores and the heads of the bolts forming the striking knobs to properly space them; 25 shows the supports for the translator comb. Detail 22 is the comb bar. The comb is shown as detail 27, and would best be made in several sections and screwed to the bar 22 by means of No. 6x3/4 machine screws. Detail 23 is the contact wire holding bars at the back of the tracker bar; 24 is the contact-wire-securing pieces shown on the top and the bottom of the tracker bar; 20 are pieces screwed inside the translator box to guide the slide L (shown best in Fig. 6).
June, 1918

All parts should be carefully made as the results will make it well worth while. All electrical connections should be sold-
ered.

**Mahogany** is specified but, of course, cheaper woods may be used if desired and stained. The best finish is shellac applied in many coats, rubbing down with sandpaper between coats and finishing up with pumice stone and oil or varnish. The final coat should be piano varnish.

If care and persistence is used in the making of the **electric piano** player here described, a vast field of pleasure will be opened to the builder which he probably never dreamed of till he has one of these machines in operation.

The best way to determine the spacing for the tracker contacts and the teeth of the comb is to buy a cheap record roll and lay them out according to this. The author could give the exact dimensions but as they run into thousandths of an inch this would only be confusing. It is a simple matter, however, if a record is used for this purpose and there is then no chance of making a mistake in the layout.

The scales shown in the various views may be cut out and used to measure any parts not dimensioned in each respective figure.

**CORRECTION IN PROF. AUSTIN'S ARTICLE.**

In the article "Theory of Tuning, Wave Lengths and Harmonics," by Prof. F. E. Austin, which appeared in the May issue, page 32, note that the inductance formula at the foot of the third column should be used only for calculating the inductance of air core coils; not iron core coils. The formula given is a general one applica-

The special counters previously used. It has also been found that the method can be used with a fork having a frequency of 100, thus reading to 0.01 second. Several meter-testing laboratories have installed duplicates of the Bureau of Standards apparatus. The electrically operated tuning fork is usually arranged with a small magn- net coil between the prongs and whose circu-

tcuit is suitably interrupted by a contact carried on the vibrating fork.

**ELECTRICALLY OPERATED TUNING FORK FOR TIME MEAS-
UREMENTS.**

This device, which has been in use in meter testing for about five years, reads directly to 0.05 second. An electrically operated tuning fork having a period of 0.05 second closes a contact which controls an electromagnetic counting device. By using a key in this circuit the arrangement acts as a stop watch. Special care has been used to drive the fork at a uniform rate. This has now been accomplished by operating it directly from a chronometer clock circuit. With slight modification it has been found feasible to use commercial "cycle counters" in place of...
Experimental Mechanics

By SAMUEL COHEN

LESSON IV.

ONE of the most important uses of the lathe in a shop is its accurate means of generating a screw or the cutting of a thread on a circular form. The thread can be cut on an outside or inside surface, both of which processes will be explained in detail.

We have several standards for various screw threads. However, in this country the general practice is to use what we call the U. S. Standard thread.

The thread of Fig. 1 shows the U. S. Standard screw thread. The pitch \( P \) is the distance of the centers between two teeth, and is numerically equal to the reciprocal of the number of threads per inch, thus:

\[
P = \frac{1}{\text{No. threads per inch}}
\]

The depth of each tooth \( D \) is numerically equal to \( D = \text{Depth} = P \times 0.6992 \).

The flat or the width of the upper portion of the tooth is equal to \( F = \text{Flat} = \frac{1}{8} \).

We also employ what we call a sharp "V" standard screw thread and this is shown in Fig. 2; this is also U. S. standard. This form of thread is generally used in small pitch threads where a large number of teeth is necessary in a given length.

The relation of pitch and depth of a sharp "V" standard screw thread is as follows:

\[
\text{Pitch} = P = \frac{1}{\text{No. threads per inch}}
\]

\[
\text{Depth} = D = \frac{P \times 0.6992}{2}
\]

The simplest way of cutting an accurate thread in a lathe is by means of employing our automatic feed on the slide rest which guides our cutting tool. In the first lesson the writer has described the feed screw which causes the carriage to move along the bed of the lathe when said feed screw is connected to the live spindle.

Like everything else, screw cutting to the beginner seems a very perplexing problem, as for instance, how to manipulate the various gears on the feed necessary to make a thread of certain pitch, etc. It is therefore the purpose of this lesson to show the amateur machinist in a simple way how to go about the work.

The first thing that we have to do is to traverse the tool along the work revolving between the lathe centers, at such ratio to the speed of the revolution as shall produce a screw of the desired fineness or coarseness, which is called the pitch, and usually express as so many threads to the inch, in length of screw.

It will now be obvious that if equal sized gears are used to connect the spindle of the headstock and the lead or feed screw which traverses the carriage and with right-hand thread. In order to cut a left-hand thread, it is necessary to cause the carriage to travel in the opposite direction to that for a right-hand thread and in order to accomplish this we introduce a fourth gear to the present simple gearing arrangement. Fig. 5 clearly shows how the addition of the fourth gear accomplishes the result. An adjustable arm or swing frame (also called a quadrant plate) is provided for holding the intermediate gears for the purpose of connecting the spindle pinion and lead screw gear. This swing frame or quadrant plate, as it is sometimes called, swivels at the end of the screw and is provided with one or two slots, having a stud and sleeve long enough to admit of two wheels side by side, and adjustable along this slot. With this means, and the swivelling motion of the quadrant plate, it will be found that any gearing may be arranged to connect the spindle with the screw. The sleeve revolving on the sliding stud of the swing frame is called the stud wheel; should there be occasion to use a second wheel on this sleeve, it will be called the pinion. Thus we have: Spindle, Stud, Pinion, Screw, or as they are frequently called—Driver Driven Driver Driven.

In Fig. 4 is shown a simple change of gears for cutting a right-hand thread, while Fig. 5 delineates two stud gears employed for making a left-hand screw. These drawings show clearly how the gears are attached to the swing frame.

We have now to consider the changing (Continued on page 120)
RADIO PROBLEM.
A peculiar phenomenon which has never been explained well is that which takes place at several points along the Atlantic Coast. There are times when a vessel is in radio communication with another and the signals gradually die out and then increase to their normal sound. A similar effect has been noted by amateurs who, when sending in one direction, can cover much greater distances.

HOW I CAUGHT A COPPER THIEF.
At the State Institution, where I am employed as electrician, we once had a motor-driven pump which was located in a field about one-fourth mile from the Institution. The line carrying the current to this pump was double O solid copper wire. Other arrangements having been made for the water supply, this pump was disused. A few days later we discovered that we had been visited by "Copper Thieves" who, evidently, knew something about "Juice," about 300 feet of wire having been stolen and the ends carefully left clear of "ground" and "short-circuits.

I then devised an electric "Thief Catcher," a sketch of which I give here. This device was located in the boiler room and a duplex telephone wire carefully "Camouflaged" about one of the O0 wires, and connected at the extremity of the line, across the line, of course.

This alarm consists of a bell, 2 or 3 dry cells, a magnet coil from an old 110 volt, D. C. rheostat, and three 16 C. F. bulbs with sockets. I have tried to make this sketch self-explanatory. Lamps L2 are placed in series with the magnet, acting as a resistance. As long as current is flowing thru the line the magnet will hold spring A. When the circuit is broken the magnet releases spring A, which then makes contact with B, completing circuit thru batteries and bell, causing the bell to ring. If one of the lamps L2 should burn out, the circuit thru the magnet would be broken, thus causing a "false alarm." For this reason lamp L1 is placed in multiple. If bell should ring and lamp L1 continue to burn, we would know it to be a "false alarm," but if bell should ring and lamp L1 cease burning, we would know that the circuit had been broken. The necessary switches were placed on the box, to cut it out of service during the day.

The thieves paid us another visit, the alarm worked, and while they were not captured, they were given a run for their life, their haste being so great that they left part of their tools behind. And that was their last visit.

Contributed by E. E. CONVER.

CURIOUS ARABIAN TIMEPIECE

Students of the history of clock-making will, we are sure, be interested in the accompanying reproduction of an early alarm-clock, common in Arabia and other countries under Mohammedan influence during the reigns of the immediate successors of the Prophet.

This mechanism, wonderfully effective in its simplicity, was in very extensive use. Many examples are found in our museums, ranging from the humble clay utensil of the camel-driver to the costly knob-kick of the sheik, with its base of Jasper or Chrysolite and its carved sockets of Silver, or even gold. The dial buja (to give it its Arabic name), consisted essentially of a series of alternate sockets, A, A, and upright, sharp-pointed pins, B, B. To set the device for operation at a desired hour, a cigarette (C) was inserted in each socket and a match (D) impaled on each pin, as shown.

The action is evident. C, having smouldered, at a known rate, down to its base, ignites D, which in turn carries the fire to the upper end of the following C. This process continues according to the number of the sockets and pins with which the particular buja is provided. The common buja of the poor seldom contained more than three sockets, the corresponding amount of sleep being the utmost they could hope to snatch from their exacting toil; but the ornate ones of the rich, who could afford to sleep as their wishes dictated, far exceeded this figure, often occurring in the sacred numbers 7 and 11, or multiples of these.

It remains to describe the sounding-device by which the sleeper is aroused. The last socket of the series (marked E in the figure) contains, instead of a cigarette, a firecracker (F) with its fuse (G) wound about the upper end of the final match. When this is ignited the more or less rapid combustion of F interrupts, momentarily, the period of silence measured off by C.

C and by the rule of contrasts almost invariably causes in the sleeper a tendency to resume consciousness.

The importation from China of firecrackers for use in buja was a well-recognized branch of trade in those times. Indeed, so important were these articles considered that we find, in the celebrated Code of Sasi Baba, severe penalties against the sale of adulterated "crackers," or those kept too long in storage.

As to the matches, those were derived in great part from—well, er—will you pardon me for a moment? I have a call on the other phone, . . .
How to Make a Water Jet Vacuum Pump

By PROF. HERBERT EDMOND METCALF

An efficient vacuum pump is a welcome addition to any laboratory, therefore one which can easily be made for a few cents and with a little patience ought to be in every amateur’s collection of apparatus. With it many interesting electrical and chemical experiments may be performed, which would be impossible otherwise.

The pump to be described is made out of glass. The equipment necessary to make it consists of an alcohol or gas flame, and a small blow-pipe. The material comprises two pieces of glass tubing, one of which will fit loosely inside of the other.

Begin by selecting a piece of the larger tubing about a foot long. In the flame draw out a constriction about one and a half inches from one end. Make the diameter of the hole thru the constriction about two or three millimeters. Put a cork in one end of the tube and direct a thin narrow flame with the blow-pipe upon a spot just above the constriction. As soon as this small spot gets hot and melts in under the force of the flame, blow into the open end of the tube, thereby blowing a hole or a bubble thru the side of the tube. Melting down the edges of the hole, and then heat one end of another small length of glass tubing the size of the first. When both are white hot stick them firmly together. They are not yet fused. Do not let the joint cool, but put a cork in the end of the tube, leaving only one opening to blow into. Direct the pointed blow-pipe flame on a small piece of paper until it bends in under the force of the flame. Then very gently blow thru the open tube until the bent-in portion is back into place. If this is done from the flame, go all around the joint in this manner finishing with a little extra care.

When finished the joint should be covered with soot in the flame, and laid aside to cool. If put on metal it will crack while cooling. If these directions are followed there will be no trouble in fusing.

The jet is now made by drawing out a smaller tube in the flame until the hole in the end is about one millimeter smaller than the constriction in the larger tube. This is done by drawing out a constriction, and then cutting it in the middle with a file. The jet is then sealed in the large tube with soot to start the constriction in the larger tube. This is done by drawing out a constriction, and then cutting it in the middle with a file. The jet is then sealed in the large tube with soot to start the constriction in the larger tube. This is done by drawing out a constriction, and then cutting it in the middle with a file. The jet is then sealed in the large tube with soot to start the constriction in the larger tube. This is done by drawing out a constriction, and then cutting it in the middle with a file. The jet is then sealed in the large tube with soot to start the constriction in the larger tube. This is done by drawing out a constriction, and then cutting it in the middle with a file.

If rubber tubing is used then it may be pinned to the small end. Once started it will continue.

The pump may be connected by a "T" to a mercury filled glass tube. This may be a "U"-tube worked by the expansion of a small bubble of air in the closed end, or by a glass tube 35 inches long, one end being put in a vessel of mercury, and the other connected to the pump. The rubber tubing on the vacuum side should be heavy walled pressure tubing in order to prevent the collapse caused by atmospheric pressure. All connections should be made air-tight with vaseline and then wired, as the slightest leakage will spoil the vacuum.

The uses of the pump are many and various. It may be used to start siphons where it is not wise to suck with the lips. It will lift water at least 20 feet or more if it will suck water thru the pump as well as air and is used to suck liquids out of inaccessible corners of vessels. It may be connected to glass tubing having platinum wires in it and used to make a study made of the behavior of electrolysis in these varying degrees of vacuum. Or, by using a small bottle connected to the pump with a rubber tubing of glass tube, water may be boiled. Also by filling this bottle half full of sulfuric ether a miniature ice machine may be made. Under a bell jar with the air exhausted, water may be boiled and frozen at the same time.

These are only a few of the interesting experiments which will instantly suggest themselves to the experimenter.

One word of caution. ALWAYS release the vacuum before shutting off or turning down the water. Otherwise the air will "blow back" from the contraction of the rarefied air in the container.

Such a machine as described, carefully made, will cost only 75 cents and raise mercury 29 inches at a barometer reading of 30 inches at sea level, and have a capacity for suction of from 2 to 3 liters of water per minute.

ANOTHER SILENT ELECTRIC ALARM CLOCK

This device is a silent electric alarm clock. Its great advantage lies in the fact that it accomplishes its purpose of waking its owner without having any noticeable effect on everyone within a hundred yards or so radius, as is the case with the common "garden variety" of alarm clock, thus saving much annoyance (profanity, possibly) on the part of those unduly disturbed.

Briefly stated, the device consists of a 25 volt ("Fon") telephone receiver, a means to rapidly interrupt its circuit with a current source at a definite predetermined hour. An Ingersoll watch with minute and second hands removed is used for the time switch, a copper wire resting on the dial at the hour figure desired. When the hour hand revolves it touches the copper wire connected at the hour set, thus making a connection between the wire and the watch case, and completing a buzzer circuit. The phone is connected to a separate binding post and the interrupter of the buzzer. The watch, buzzer and a battery switch may be mounted inside a cigar box, and the two sets of binding posts on the side. The current source may be a dry cell, or better a four or six volt storage battery, possessed by most experimenters. The buzzer should be packed in cotton to deaden the noise.

In operation, the watch is removed, wound and set, and then replaced. The copper wire is then made to rest on the proper place; for instance if it were desired to set the alarm for seven o’clock, the wire would be placed on the third hour hand. The receiver may be placed under the pillow or at the head of the bed. You know the kind of a discipline the Kaiser’s boys are brought up to—they wear special crampons on their faces at night to train their mustaches up, like Papa Wilhelms’. So perhaps, if your discipline is rigid, you won’t object to wearing a head-band while you sleep, which will hold George’s “silent alarm” right against your ear. Selah.

Contributed by GEORGE F. GEIS.

Cigar Box.

Do You Wish for a Silent Alarm Clock? Here’s How One Can Be Made. Ask an Ingersoll, Clip Off the Minute Hand, Arrange an Adjustable Contact Over the Dial, and Connect Up This Innocent-Looking Combination to a Buzzer and Telephone Receiver. You’ll Wake Up—Oh! Yes!

The Old Bunsen Burner

HOW dear to my heart is the old apparatus,
The chemistry stuff that I'm using no more!
The beakers, the pincers, the test tubes and holders,
And all the old stuff that my damage bore;

CHEMICAL HINTS FOR THE EXPERIMENTER.
Never grind phosphorus and potassium chlorate in a mortar or an explosion will result. Sulfur and potassium chlorate also are liable to produce an explosion when ground. It is safest never to grind two substances together unless advised to do so by an expert.
Don't open a bottle of ether near a naked flame. Ether vaporizes very rapidly and the vapor when mixed with air is explosive. The vapor is heavier than air and will roll along the floor to a flame even if it be on the opposite side of the room.
When experimenting with hydrogen always be sure the bottle contains no air mixed with it. Collect a test-tube of the purest gas and ignite. If it burns quietly it is safe to use. If it explodes it is very dangerous to use.
Never add water to acids, but add the acid slowly to the water, stirring at the same time.
When you are thru using any apparatus clean it thoroughly and return to its place. It may take quite a while to clean anything that has been standing, whereas it would take but a few seconds to clean if it is done immediately after the particular experiment.

The pneumatic trough and the jars that stood by it.
The flasks, and the stoppers with two holes or four;
The Kipp generator, the hoods that were nigh it.
And 'em the old burner that stuck in the drawer.

The old Bunsen burner, the leaky old burner,
The rust-covered burner that stuck in the drawer.

The rust-covered burner I hailed as a treasure,
For often at noon when returned to the lab,
I found it the source of an exquisite pleasure.
The sweetest and best that a student can nab.

How ardent I sneezed when it started a-burning,
And quick to the top of the ceiling twould go;
Then soon my slipper clucked to mock terror turning,
And smelling like thunder, it gave off C.O.

The old Bunsen Burner, the leaky old burner,
The rust-covered burner, it gave off C.O.
The first time I used it, it burned me quite badly.
The second, it blew up and gave us a fright.
The pupils around me were murmuring sadly.

THE CHEMICAL HINTS FOR THE EXPERIMENTER.

An Exceptionally Fine Students Who Learned Practical Electricity with This Well Selected Apparatus Are Now Electricians, Engineers, and Other Practitioners of the Electrical Art.

ELECTRICAL EXPERIMENTER
HERE is a novel means of transmitting over radio, telegraph, or telephone systems, maps, drawings, etc. The idea is to have two of these plotting instruments exactly alike, one instrument at each end of the line of communication. The sender, making his sketch and placing it on the board, would retrace the sketch with the steel needle on the movable slider, by placing the needle at a starting point of the drawing and noting what the figures read on the beam scale and circular arc scale, and then placing the needle to the next intersecting line or angle on his instrument to correspond to the figures received. The arm is then pressed downward, making an impression of the needle on the paper and thus by drawing from point to point, as received, an exact reproduction of the drawing or sketch can be made. In order to get irregular lines or circles it requires the impressions to be made more closely together.

Carbon paper could be placed beneath the receiving copy, thus duplicating the drawing. Duplicate maps can be placed in the instruments and the exact location of a line of trenches, batteries or points of importance could be communicated over any distance. Any combination of figures or letters can be used on the scales. It has been recommended by military experts.

TREMENDOUS FORCE EXERTED BY SHORT-CIRCUIT.

"Some indication of the enormous force exerted when a short-circuit takes place close to a station was given recently when cable trouble occurred on the lines of a large Western company," writes George W. Leffean in the Electrical Review. "In searching for the damage done a slight bulge was observed on the joint sleeve, where the cable joined a submarine cable. The joint was opened and it appeared that the conductors had been crowded forward into the joint 2 in. (5.1 cm.)."

On testing the damaged submarine cable from the street end it was found that the conductors showed all three legs short-circuited and grounded, while a test from the station end showed the three conductors short-circuited but free from ground, indicating that the cable had burned apart. Resistance tests indicated that the failure had taken place three-quarters of the way between the station and the street end. The cable was dug up at this point, the break discovered and the cable found to be damaged for a distance of about 4 ft. (1.2 m.), with no damage to adjacent cables.

A photograph of a new and highly efficient map and sketch transmitting instrument shows its two graduated scales permitting very rapid location of the map co-ordinates.

A SIMPLE HELIOGRAPH.

The heliograph is handy for "Boy Scout" camping parties and the like, enabling them to use the sun's rays to keep in touch with one another over considerable distances.

This set works on the same principle as the more expensive ones built for the Army. An ordinary strap key is utilized in this design, a small hole being drilled in the center of the lever and taped to take a stirrup clamp from a head band. Secure a small pocket mirror, and make a small depression in each side of the rim to permit the mirror to be balanced between set screws V-Y. The mirror must also have an unsilvered spot C, about 1/8-inch in diameter made at the center. This spot retains its position thru all movements in any place.

The operation is as follows:—the rays of the sun are brought on to the distant station by turning the mirror A until the operator, looking thru the unsilvered center of mirror sights the distant receiving station. The heliograph is now "set" and signals are made by pressing and releasing the key B, the same as with regular telegraph instruments.
How to Build a Spark Coil Ozonator
By FREDERICK VON LICHTENOW

IT is a well-known fact that the electric discharge across an air-gap liberates "ozone" freely, and further, that the production of this ozone may be many times increased by allowing the discharge to pass between metal sheets, preferably tinfoil. Making use of these facts, the simple "ozonator"—attachment here shown constitutes a practical piece of auxiliary apparatus for any spark coil of 1-inch rating or more.

Two oblong sheets of corrugated packing board of equal dimensions; two sheets of heavy tinfoil cut to approximately the same size, but slightly longer; two pieces of medium gage copper wire, a wooden or cardboard box (without cover), and a cone-shaped tube of some material, other than metal, form the essential parts for its construction (Fig. 1).

An application of paste or shellac secures the tinfoil to the packing board, which merely serves as a support for the foil. The foil extensions—due to its being longer—are pasted around over the exposed corrugations at either end of the packing board, ending with the back edge of the latter. The whole is then fastened to the wire by running the same thru the foil into one of the centermost corrugations, at the same time furnishing the necessary electrical contact between wire and foil (Fig. 2).

The distance between the foil sheets and their respective size are governed entirely by the rated spark length of the coil employed, with a proportionate amount of generated ozone as a consequence. They should, at any rate, be placed in a position parallel to one another (in the same plane) and at such a distance where a silent discharge (in reality there is a heavy "brush-discharge," consisting of a stream of violet-colored spark-threads passing between the foil sheets, which can be easily ascertained in a dimly-lighted room) manifests itself, allowing only an occasional spark to pass. (This distance is somewhere in the neighborhood of one-half of that of the spark discharge between needle points.)

The cone is secured to the box by being pushed thru the opening on top of the latter from the inside until it fits tight. Some friction tape is finally run over the seams of the box as well as around the joint of the latter, with the cone and the whole placed over the generating apparatus (Fig. 3).

The box should be only slightly wider than the top of the spark coil, just wide enough to allow air to pass thru, and there should be ample room inside of it to clear the foil sheets all around by several inches.

An important point is that the packing board be perfectly straight and the tinfoil applied smoothly, in order to insure uniform distribution of the electrical stress between the foil surfaces. Otherwise, the discharge will localize upon certain spots, resulting in a decreased ozone output.

The "ozonator" is used for air purifying, inhaling or experimental purposes in general. If an "Electro-Bulldog" coil is available then a taller box will be required and the same slit over the spark coil as well. Semi-circular cuts on both sides for the passage of air and two small holes on one side of the box for the insertion of the primary wires are to be provided (Fig. 4). The author has a zinc spark gap mounted across the coil secondaries, which is of a great advantage, in that it permits of a far finer adjustment of the sheet electrodes than could be possibly had by using the regulation style of binding post terminals.

Good results are obtained with both types of arrangements as outlined in the foregoing.

A TELL-TALE FUSE BLOWOUT.

It is sometimes convenient to be able to tell at a glance into a fuse cabinet which fuse has just blown out, even if one is not familiar with all the circuits in the plant. A New England inventor has recently patented a fuse which visibly indicates its condition when it needs replacing.

The sketch shows the construction of his invention. A shunt wire, of high resistance, passes thru the fuse and is connected to the end caps. This shunt carries very little current until the true fuse wire is blown. An indicating spring strip outside the shell is held down by a filament connected to a small mass of some material easily melted by heat. A wire gauge cage incloses the melted material to prevent it being blown thru the hole in the shell, and is placed close to the shunt wire.

When the fuse blows a rush of heavy current passes thru the shunt, bringing the wire to a high temperature, thus melting the holding material and releasing the indicating spring strip.

HOME-MADE "OMNIGRAPH" OF WIDE RANGE.

Often indeed does the amateur wish for a
omnigraph, but almost as often does he
do without one because of the expense. So
I submit herewith an easily made and in-
expensive omnigraph which I find does the
work.

The instrument consists primarily of a
tin can, covered with heavy paper, in which
are cut holes corresponding to the dots and
dashes of the code. If this breaks the cur-
rent since one wire of the circuit is con-
ected to a series of springs making contact
through the holes and the other the tin can.
A switch is connected to these springs in
series with a sounder or buzzer, thus trans-
lating any one of the messages.

With This Home-Made "Omnigraph" You
Have Available a Wide Variety of Radio Sig-
als Which Can Be Changed Instantly by
Moving a Switch.

This instrument may be run in various
ways, the best of which is by an electric
motor. However, it may be operated by a
spring motor or even by hand, the number and
size of the pulleys depending upon the
speed of the driving motor. If an electric
motor is used, a rheostat may be inserted to
vary the speed. If it is so desired, the
cylinders may be made interchangeable, thus
giving the instrument a wider range of use
albeit it is surprising how much can be
placed on a single one.

INSULATED STOOL FOR "TESLA STUNTS."

A stool like this is a necessity for the
"Ham" who is experimenting with high-
frequency or frictional electricity. All that
is needed is a good strong board about one
and one-half feet by two feet, four strong
bottles of the same size (I used soda pop
bottles), and two wooden cleats.

Four holes are bored in the large board,
one at each corner. They should be just

Efficient Static and High Frequency Insulat-
ing Stool.

The advantages of this stool are that it
can be made easily and at little cost from
almost anything, that it will stand a high
voltage, and that it can be easily taken
apart; all that has to be done is to draw
the bottles out of the holes.

VARIABLE CONDENSER CON-
TROL FOR PANEL SETS.

As most radio receiving sets are now
made in the panel type, and most variable
condensers work best when mounted
upright, I suggest these methods of mounting
them.

The knob is removed from the condenser
and mounted on the panel. It connects with
the condenser shaft by means of a piece
of soft rubber tubing inserted as a flexible
shaft. Also it is thoroly practicable to use
a fairly stiff spiral spring as a flexible shaft.

A NOVEL "DARK ROOM" LAMP.

I present herewith a drawing of a novel
"dark room" lamp, which I have been using
for some time. The light is adjusted by
turning the knob. Any small jar with a
screw top will serve the purpose. The cen-
ter part of the metal cover is cut away and
a wood or fiber block fitted to it. The re-
ceptacle is dip in melted wax after the
lamp is in place. Do not use too much wax
else the liquid may get too hot. I use
about one teaspoonful in a jar 3 inches
diameter, 4 inches high. The solution is
composed of red ink and water. I use this
lamp with films and find it safe.

TESTS FOR WATER.

Hard or Soft Water Test.—Dissolve a
small bit of soap in alcohol, let a few drops
fall in a glass of water; if the water turns
milky it is hard, if not it is soft.

Alkaline Test.—Immerse litmus paper dip
in vinegar in the water, if the paper turns
to its original color, the water contains no
alkaline or earthy matter.

Test for Carbonic Acid.—Take equal parts
of water and lime water, on mixing If a
precipitate is seen, the water contains car-
bonic acid.

Test for Iron.—Boil a few nut-galls in
water, then add some to the water to be
tested; if the water turns grey, iron is
present.

Test for Lime.—Put two drops of oxalic
acid in a glass of water, then blow on it;
if it turns milky, lime is present.

A HOME-MADE HYGROMETER.

The Hygrometer, as we know, is an instrument for measuring the quantity of moisture in the atmosphere. It depends on the property possessed by some substances, of readily absorbing moisture from the air, and being thereby changed in dimensions or in weight. Of this kind is the Hygrometer of Saussure, in which a hair, that will expand and contract in length accordingly, as the air is more or less moist, was made to move an indicator. Similar instruments were also devised by Deloc and J. F. Daniell.

The writer recently constructed a simple Hygrometer, with which he could tell short the approach of a rain sixteen to twenty-four hours in advance. A description of the instrument follows: Referring to sketch: S, S' and S" form a wooden support. (The experimenter can construct this to suit himself, some preferring to make a more fancy one than others.) W, is a small, stiff wire, about 3" long and attached to a thin piece of wood which has been planed down to 3" by ½" by 1/16". A cat-gut string is then procured—C. (Such as the "A" string on a violin.) This string is fastened securely at the top of the support, by boring a small hole, inserting the string and then plugging the hole with a small wooden plug. X. The free end of the wire, before described, is then bent into a small loop about ¾" in diameter and is shown at L.

Next we thread the string thru the loop and give it one-half turn around the wire. It is then lead thru the indicator "R" by boring a small hole of slightly larger diameter than the cat-gut. The hole should be bored as near as possible to where the wire is secured to the indicator. The cat-gut string should now be pulled taut and plugged in the bottom of the support at "X." A small nail P is then driven into the support S to act as a stopping point. Its duty is to allow the indicator to swing about in one direction only. "Pair" and "Rain" may now be painted on the indicator and our mechanical weather-man is completed.

The builder may desire to construct a more elaborate support which he can do by making a small wooden house and decorating it with pieces of bark to give a novel log-cabin effect. However, the front must be constructed open to allow the indicator to swing around. The instrument is then placed in some open but sheltered place and is ready for use.

The action is as follows: When the cat-gut is taut it exerts a twisting motion on the wire and tends to twist the end of the indicator marked "Rain" against the stopping point "P." When there is a great deal of moisture in the atmosphere the cat-gut string will become slack and allow the end marked "Rain" to swing half way around.

In this way we can all become modern weather prophets.

CASTING BARS OF SOLDER.

In the drawing herewith (a) is a gong from an electric bell with a dent (c) bent in one side of it with a pair of pincers: (b) is a rivet past thru the hole in the gong, while (e) is an iron rod riveted to (a) at (d). A pea shooter makes an admirable substitute for the iron rivet. Here (f) is a wooden handle in which grooves (hh) are made. The solder is poured from the ladle into these grooves. Sandpaper the grooves well and the solder can be easily removed.

Contributed by ALBERT RUFF.

FINE INK AND MAGIC PAPER.

Fine Ink.—This experiment is most effective in a dark room. Dissolve ½ teaspoonful of potassium nitrate in a little water (about ½ teaspoonful). Now use this liquid as an ink, writing on unglazed paper any design, making broad and heavy strokes and be sure to connect all lines. When the paper is thoroughly dry, apply a light to the end of the writing—putting out any flame that arises. If all directions have been carefully followed a glowing spark will travel the length of the design. The effect is most mysterious and best results are obtained by using soft paper and writing all lines broad and heavy.

Magic Paper.—If some people don’t believe you can write black lines with plain water show them this experiment.

On a sheet of writing paper rub this mixture—equal parts of tannic acid (powder) and tannic ammonium sulfate thoroly mixed. After the mixture has been rubbed into the paper blow off all remaining particles. The paper is now ready. Write with a piece of dip in water and black lines will appear.

THE "REAL" WINE AND WATER TRICK.

By Albert H. Beiler.

Many of you have heard of or seen the so-called "wine and water trick" wherein a liquid, presumably water, is poured from a bottle into different glasses, which are apparently empty, and produces wine (don’t drink it, for the love of Mike!) in some glasses and water in others. Various chemicals are used to produce this effect. One way is to have a crystal of potassium permanganate, K Mn O₄, in one glass, a solution of oxalic acid in another, and two glasses empty. Warm water when poured from a bottle into three of them will produce no result, but in the K Mn O₄, glass a red color results. When all three glasses are mixed together the oxalic acid decolorizes the K Mn O₄. Still another method utilizes potassium-sulpho-cyanide and an iron salt, and a third method, phenolphthalein.

The writer has tried all of these with varying success. And then one day we talked to one of these wonderful prestidigitators (oh, yes, it’s in the dictionary) and got the only and original formula for the real wine and water trick. You have only to try it to know it’s the REAL one.

First secure four glasses. Put a very small drop of Fe Cl₃ (iron chloride) in each of two of them, and fill another half full of H₂C₂O₄ (salicylic acid). The other one remains empty. The glasses with the chemicals should be farthest from the Audience. Fill a flask with a solution of OH₃H₂C₂O₄ (salicylic acid). The table shows how to perform the separate operations of the trick in their proper order. That is, first pour some liquid from the flask into glass No. 1. Result—colorless. Then into No. 2. Result—Red. Then into No. 3. Result—colorless. Then into No. 4. Result—Red. Two and four combined give colorless.

Arrangement of Four Glasses as Used in Producing "Wine and Water Trick" as Described by Mr. Beiler.

Wrinkles, Recipes, Formulae

EDITED BY S. GERNBACK

To write down the one hundred and eleventh formula in a formula drawer the editor of this department was induced to write down an article that might be of some assistance to the electrical experimenter in his day-to-day work. The article in question, entitled "Wrinkles, Recipes, Formulae," is intended to be of use to those who make a practice of experimental work. The following article is an excerpt from that source.

The "REAL" WINE AND WATER TRICK.

By Albert H. Beiler.

Many of you have heard of or seen the so-called "wine and water trick" wherein a liquid, presumably water, is poured from a bottle into different glasses, which are apparently empty, and produces wine (don’t drink it, for the love of Mike!) in some glasses and water in others. Various chemicals are used to produce this effect. One way is to have a crystal of potassium permanganate, K Mn O₄, in one glass, a solution of oxalic acid in another, and two glasses empty. Warm water when poured from a bottle into three of them will produce no result, but in the K Mn O₄, glass a red color results. When all three glasses are mixed together the oxalic acid decolorizes the K Mn O₄. Still another method utilizes potassium-sulpho-cyanide and an iron salt, and a third method, phenolphthalein.

The writer has tried all of these with varying success. And then one day we talked to one of these wonderful prestidigitators (oh, yes, it’s in the dictionary) and got the only and original formula for the real wine and water trick. You have only to try it to know it’s the REAL one.

First secure four glasses. Put a very small drop of Fe Cl₃ (iron chloride) in each of two of them, and fill another half full of H₂C₂O₄ (salicylic acid). The other one remains empty. The glasses with the chemicals should be farthest from the Audience. Fill a flask with a solution of OH₃H₂C₂O₄ (salicylic acid). The table shows how to perform the separate operations of the trick in their proper order. That is, first pour some liquid from the flask into glass No. 1. Result—colorless. Then into No. 2. Result—Red. Then into No. 3. Result—colorless. Then into No. 4. Result—Red. Two and four combined give colorless.

Arrangement of Four Glasses as Used in Producing "Wine and Water Trick" as Described by Mr. Beiler.

OXIDES OF CARBON—CARBON DIOXID.

VAN HELMONT, an alchemist of the seventeenth century, noticed that the gas obtained from burning wood, fermentation, or the action of an acid on limestone, possessed different properties than ordinary air, in that it was capable of extinguishing fire. He designated "wild gas" as an appropriate name for it. Van Helmont posset an idea that vegetation was dependent on growth upon water alone. He set out to prove to his own satisfaction that this was the case, and after carefully weighing a small willow tree of 5 pounds and planting it in a pot containing exactly 200 pounds of dry earth, he watered it with rain and distilled water, and in five years he removed the tree and again weighed it, finding that its weight had increased to 169 pounds and 3 ounces, and that the earth had only depleted 2 ounces in weight. His ignorance of carbon dioxide and its functions in the air, at this time, made him believe that the tree actually fed on water alone.

Black obtained it from the carbonates of sodium and potassium, in which he said it was "fixt," and called it "fert air." Lavoisier recognized the chemical nature of the gas and proved its composition to be carbon and oxygen. Dalton showed that the molecule consisted of one atom of carbon, united with two atoms of oxygen, thus illustrating its volume composition. Faraday was the first to quantify it.

Names—Carbon dioxide: carbonic acid; carbonic acid gas; carbonic anhydride. Absorption—Carbon dioxide is a free and uncombined in the atmosphere, of which it forms at least 0.00% to 0.005%, the average being about 4 parts in 10,000 of air. It is found in all terrestrial waters, some springs being heavily charged, and is given off in large quantities from the earth in many volcanic regions. It collects in caves, mines and wells, and is quite often termed "chokes-damp." Combined with water, it forms carbonic acid, still more abundantly distributed. The principal one of these compounds is carbonic carbonate, which, as marble, limestone, and chalk, is one of the most abundant of minerals.

Preparation—1. When heated, carbonates and bicarbonates yield the gas according to the following equations:

\[ \text{CaCO}_3 + \text{CO}_2 \rightarrow \text{CaO} + \text{CO} + \text{H}_2\text{O} \]

2. When small quantities are desired it may be rapidly and conveniently prepared from a carbonate and an acid. In general, most acids will act on any carbonate and liberate carbon dioxide. Carbonate (Marble, \( \text{CaCO}_3 \)) and hydrochloric acid is most suitable for preparation in the laboratory.

\[ \text{CaCO}_3 + 2\text{HCl} \rightarrow \text{CaCl}_2 + \text{H}_2\text{O} + \text{CO}_2 \]

Carbonic acid is probably the first product, but, being very unstable, at once breaks up, as shown by the equations. A high temperature will cause decomposition of carbonates into carbon dioxide and the oxide of the metal. Heat will decompose oxalate also, liberating carbon dioxide and carbon monoxide and leaving the metallic oxide, thus:

\[ \text{CaCO}_3 \rightarrow \text{CaO} + \text{CO} + \text{CO}_2 \]

3. When a current of air is past over red-hot carbon the product is carbon dioxide, provided the air has been kept in excess. This and the method by heating a carbonate are used for furnishing the gas in the manufacture of carbonates on a large scale.

Carbon dioxide is formed whenever carbon in any form or its compounds with absorbing so much heat as to produce an intense degree of cold, thereby causing a portion of the liquid to solidify to snow-like flakes. It solidifies at about —80 deg. by its own evaporation.

It is quite beneficial as a beverage, which is known as "soda-water," and is a solution containing about 3 volumes of the gas in water.

(Chemical): It is a non-supporter of combustion and is not burned by ordinary sodium and potassium burns in it. This property may be illustrated by lowering a lighted splint or taper into a vessel of carbon dioxide, or pouring it down an inclined board upon which is placed a number of lighted candles.

A small cent of carbon dioxide in the air prevents combustion; thus it is a far superior fire extinguisher compared to nitrogen.

It is not respirable, because it shuts out the oxygen necessary for respiration.

Its action on hydroxides is to form carbonates. It is a very stable compound which is decomposed only at a temperature of 1,300 degrees, or by the continued action of the electric arc, yielding carbon monoxide and oxygen.

In the dry state it is neutral. In aqueous solutions it is capable of coloring blue litmus a faint red, which disappears on drying. It does not neutralize alkalies.

Physiological Action of Carbon Dioxide.

This is a very interesting chemical action which is continually taking place in the human system. (Refer to Fig. 118.)

We breathe in oxygen (the chief constituent of the atmosphere), which is reduced from about 21% to 16% by heat. The exhalations also contain nitrogen, argon and surplus oxygen. About a quarter of the oxygen has been consumed in heating the body and oxidizing its products, which are mainly compounds of carbon, nitrogen, hydrogen and oxygen. The union of carbon, hydrogen, etc., with oxygen takes place in all the tissues and in all parts of the body, even on the surface. Oxygen is taken into the lungs and passes from there thru the thin membrane into the blood, by reason of the attraction it has for the hemoglobin or the red corpuscles. With these corpuscles it forms a compound oxy-hemoglobin, and thus circulates to all parts of the system.

The rational molecular formula of the hemoglobin is not known. Peyer suggested the empirical formula: \( \text{CN}_{21}\text{H}_{36}\text{O}_{21}\text{N}_{2} \text{Fe} \). Jaquet has suggested a different formula: \( \text{CN}_{20}\text{H}_{33}\text{O}_{19}\text{S}_{2} \text{Fe} \). It is very

"Electrical Laboratory" Contest

In this issue we publish an interesting story with an excellent photo, describing one Amateur Electrician's experimental laboratory. Now "Bugs"—we want to publish a similar article each month. Here's our proposition: Why not write up your "Electrical Lab," in not more than 500 words. Dress it up with several good, clear photographs. If we think it good enough we will publish the article in display style and pay you well for it. The remuneration for such articles will range from $5.00 to $10.00. And "Bugs"—don't forget to make your article interesting. Don't write—"I have a voltmeter, an ammeter, a switchboard," etc., ad infinitum. For the love of Pete put some punch in it! Tell us what you do with your instruments and apparatus. You don't mean to tell us that every Experimenter does exactly the same thing. We' know different—but from the general run of such articles which we have received in the past, one would naturally think every "Lab," exactly alike. Remember—send a photo of YOURSELF along. Typewritten articles preferred.

A GROUP OF REPRESENTATIVE AMERICAN AMATEUR LABORATORIES.

Electrical Laboratories of, 1—Charles Stewart, Cadiz, Ohio. (Prize Winner); 2—Seefred Brothers, Los Angeles, Calif.; 3—Joe Haskell, Jr., Cliftondale, Mass.; Radio Laboratories of, 4—Paul Williams, Shorewood, Wis.; 5—H. F. Inns, Jr., Bellflower, Ill.; 6—Thomas J. Donohoe, Columbus, Ohio; 7—Maynard Bodley, St. Paul, Minn.; 8—George W. J. Miller, Manitou, Colo.; 9—Ralph V. Kornhak, Braddock, Pa.; 10—H. Bamborough, Highland Park, Ill.
Electric Hair-Brush.  

(No. 1,258,375; issued to V. V. Stewart.)

An electrical hairbrush having for one of its objects the provision of a device especially adapted for straightening and drying hair. It is provided with an electrically heated plate to which are attached a plurality of metallic teeth, that are heated by the plates, whereby the hair of a person may be readily dried and straightened. This metal plate is enclosed within the hollow casing as shown, a suitable electrical heating coil being placed in position over the plate.

Electric Fountain.

(No. 1,255,711; issued to Newton Crane.)

An electrically operated and illuminated fountain suitable for interior decorations. It contains sufficient water to operate for long periods without hose connections, the water from the jets falling into a basin and reservoir, from where it is pumped up thru the jets again. An electric motor rotates the pump concealed in the hose and the water thru the revolving jets, while changing color dyes cause the jets to take on beautiful hues.

Primary Battery.

(No. 1,258,266; issued to Edward Sokal.)

The battery employs as an electrolyte a single fluid, such as a solution of ferric chloride. The electrodes are composed of carbon and zinc, respectively. This solution acts not only as a solvent on the zinc, but also as a depolarizer. No porous diaphragm is used. The battery has a high E.M.F. of 1.5 volts. Circulation of the electrolyte thru the battery is provided for by virtue of a small motor-driven pump.

Variable Radio Condenser.  

(No. 1,258,423; issued to F. Lowenstein.)

A very clever variable condenser for use in radio or other circuits, having its rotary plates cut off at such different angles as to produce a logarithmic capacity variation characteristic. In the ordinary rotary variable condenser equal angular movements of the movable plates within the range of the instrument, produce unequal percentage variations in capacity. For certain radio requirements it is desirable to have a logarithmic characteristic condenser, but heretofore it has been a complicated matter to design and build them owing to the peculiar form of moving plate required. By the present type this result is simply achieved, equal angular movements of the rotary plates producing equal percentage changes in capacity.

Talking Motion Pictures.  

(No. 1,254,684; issued to Elmer Lewis.)

This patent aims to provide means for synchronously producing sound causing to be produced supplemental musical sounds in conjunction with motion pictures. The inventor provides a means such that the several musical and sound producing instruments shall be automatically operated by the motion picture itself. To do this he photograph on the film itself a series of lines or marks, as needed in the drawing, which run parallel to the length of the film. Each line may represent a certain note or operating pedal. The light from the “movie” projector passes thru these transparent “sound marks” and is intercepted at the screen, falling upon a series of exposed, separate, selenium cells. An individual cell is provided for each “sound mark” on the film, and each ray of light is directed by a system of slots and guides to a shunt or a register with its corresponding cell.

Motor Player for Stringed Instruments.  

(No. 1,258,465; issued to W. A. Richter.)

A motor-operated hand manipulator for playing device for stringed instruments, such as violins, banjos, mandolins, guitars, etc. The device consists of a rotatable cylindrical sounding mounted on the free end of a flexible shaft connected with a small electric motor at one end. By means of the handle sleeve provided, the rapidly rotating disc (which for playing the violin is covered with horse hair) can be brought successively into contact with the musical strings to be vibrated.

Duplex Wireless System.  

(No. 1,256,889; issued to Lloyd Espenschied.)

This idea covers a scheme for simultaneously transmitting and receiving radio signals on a common aerial. Successful duplex radio communication is provided for by utilizing carrier waves of different frequencies for transmission and reception, also by neutralizing the inductive action of the transmitting system proper on the receiving system by means of balancing circuits as indicated. This is done by circuits being linked inductively with both the transmitting and receiving circuits. The function of the balancing circuit is to neutralize, with respect to the receiving circuit, the effect of the transmission current flowing in the radiating aerial circuit.

Radio Receiving Circuit.  

(No. 1,257,672; issued to Elmer E. Butcher.)

A scheme whereby the inventor claims to greatly increase the sensitiveness of the detector used in radio-telegraphy or telephony, so as to amplify minute impulses of weak energy and for the purpose of receiving radio signals. He attains this object by providing a detector circuit, such as one employing a three electrode valve detector, in which the highest possible potential output can be obtained from a given amount of energy received is imposed upon the detector. To accomplish this, the secondary circuit contains practically nothing but inductance.

Receiver of Radio Oscillations.  

(No. 1,257,637; issued to Roy A. Sokal.)

Method of detecting radio oscillations or signals, and by a peculiar and novel circuit may be used to increase the efficiency of such detecting means where it is tuned to the group frequency of the received signals. The usual detector circuit is provided in general; two variable inductances with suitable capacities are connected up in shunt with the detector. The ratio between the auxiliary inductances and that of the loose coupler secondary may be such that they may have about 1,000 times the secondary value.

Dry Cell Renewal Device.  

(No. 1,257,962; issued to E. H. Becker.)

This patent relates to a novel means for reviving dry cells after the same has stood idle for a period of time or has been in use and has become weakened. As shown in the sketch, two or more soluble metal (zinc) capsules are embedded in the cell when manufactured, these capsules containing either metal or electrolyte. The capsules are made of a material which is positive to the negative element, and of varying thickness so that the action of the battery will automatically liberate the contents at any predetermined time, depending upon the results desired. These capsules are electrically connected to the zinc shell of the dry cell by copper wires.
Under this heading are publish electrical or mechanical ideas which our clever inventors, for reasons best known to themselves, have as yet not patented. We furthermore call attention to our celebrated Phoney Patent Office for the relief of all suffering daffy inventors in this country as well as for the entire universe.

We are revolutionizing the Patent business and OFFER YOU THREE DOLLARS ($3.00) FOR THE BEST PATENT. If you take your Phoney Patent to Washington, they charge you $20.00 for the initial fee and then you haven't a smell of a Patent yet. After they have allowed the Patent, you must pay another $20.00 as a final fee. That's $40.00! WE PAY YOU $3.00 and grant you a Phoney Patent in the bargain, so you save $43.00!! When sending in your Phoney Patent application, be sure that it is as daffy as a lovesick bat. The daffier, the better. Simple sketches and short descriptions will help our staff of Phoney Patent Examiners to issue a Phoney Patent on your invention in a jiffy.

Prize Winner. THE "DACHSHUND 500 MILE SHELL." Here's a New and Wonderfully Powerful Long Range 500 Mile Shell Which the Allies Can Use In Their Present Howitzers and Siege Guns and Beat "Fritz" at His Own Game. The Big Guns Ordinarily Fire Shells 20 to 25 Miles. By Installing a Dog-Tread-Power in Each of 5 Shells and Raising a Pair of "Dachshunds" in Each Shell Before Firing, With a Piece of "Kufur" Sausage in Position as Shown, the Range Can Be Increased to at Least 500 Miles! The Dog-Power Is Transmitted by Level Gears to the Propeller on the Front of the Shell. Offer This Timely and Heretofore Unthought of Invention to General Foch and His Engineers to Retaliate Against the "Hun," for I Believe "Fritz" Really Finds His Mark at Paris by Utilizing "Paris-Bred," French Poodles in Those 76 Mile Range Shells. As History Proves, a Dog Will Find His Home, Even Tho He Has to Travel Hundreds of Miles. Then He Will Wag His Tail and I Suggest That the "Time Fuse" Be, Therefore, Attached to It. Inventor, Edgar T. Rigg, Jr., Baltimore, Md.

Electric "SCHOOL-ROOM COAL-SAVER." Being a True Friend of Dr. Garfield and the Fuel Administration, I Herewith Dedicate to them and the American Coal-Famine Sufferers a Brilliant Idea Which Struck Me Last New Year's Night, When I Had Speeded Up My Mental Faculties by Imbibing 1½ Milkshakes, 15 Walnut Sundaes, and 4½ Banana Splits. Here It Is: Install in Every School-Room Through the Land My Compress Air-Electric Generating System as Illustrated. As Students Arise to Recite and Sit Down, Especially on a Tack, They Will Work the Seat Bellows; This Compresses Air Thru the Pipe System to the Air Tank; Compress Air Runs Engine Belted to Dynamo and Storage Battery. Electric Heat and Light Is Thus Obtained Absolutely Free and in Great Abundance. Think of It! 15,000,000 School Children Rising and Falling on My Pneumatic-Electric Generators! "Doc" Garfield Should Give Me a "Croix de Bituma"—What? Inventor, John Plumett, Newton Highlands, Mass.
The "Oracle" is for the sole benefit of all electrical experimenters. Questions will be answered here for the benefit of all, but only matter of sufficient interest will be published. Rules under which questions will be answered:

1. Only three questions can be submitted to be answered.
2. Only one side of sheet to be written on; matter must be typewritten or else written in ink, no penciled matter considered.
3. Sketches, diagrams, etc., must be on separate sheets. Questions addressed to this department cannot be answered by mail free of expense. Correspondents will be informed as to the fee before such questions are answered.

4. If a quick answer is desired by mail, a nominal charge of 25 cents is made for each question. If the questions entail considerable research work or intricate calculations a special rate will be charged.

RELATIVE FORCE OF MAGNETIC ATTRACTION AND REPULSION.

(926) J. C. Kane, Detroit, Mich., writes:

Q. I. With the apparatus shown in the diagram I find that the magnetic attraction between 2 "unlike" poles is much greater than the repulsion between 2 "like" poles. Why is this?

A. I. Referring to your diagram of the arrangement of four electro-magnets each having the same number of lines of force per pole and having these electro-magnets in pairs, one pair having a north (+) and (-) south pole, and the other pair having two north (+) or south poles (—) and pivoted as shown, the force exerted by the magnets (+) and (—) appears to be greater because of the law of inverse squares. This law says that the force exerted between any two bodies varies inversely as the square of the distance between these bodies.

Furthermore, when the current is turned on, producing unlike poles, attraction at once begins to take place. However as the attraction is taking place the distance between each pole is becoming less and less, hence the force becoming greater and greater. When the poles are magnetized (+) or (—) or (—) the converse action takes place. The distance between the poles becomes greater and greater, causing the force to become less and less. Thus it is seen that while the two original forces (that is, the forces exerted when the distance was the same) are the same, one increases and the other decreases according to the natural law.

The force of attraction is always equal to the force of repulsion, but in the case cited by you we must make note of the following facts: If the forces were of repulsion, they would cause the pivot-arrangement to be deflected thru a certain angular distance. Now if we increased this angular distance by a very small amount and changed the polarity of the magnets, the pivoted bar would not be attracted, but if we placed the bar at the same angular distance that it was repelled thru, and the changed polarity remained the same, the bar would at once be attracted. In your case, you began with the pivoted bar at a certain distance away from the poles.

WIRELESS TEXT-BOOKS.

(927) Chas. H. Hook, Mt. Washington, Pittsburgh, Pa., writes:

Q. I. What good wireless text-book can you recommend which give the design details for high power radio stations?

A. We believe that you obtain a copy of Professor Johann Zenneck's book entitled "Wireless Telegraphy" which our "Book Department" can supply at $4.15 prepaid. This book is one of the best that has appeared, and contains many practical chapters on the design of high power radio equipment. Also you will find Dr. J. A. Fleming's classic work entitled "The Principles of Electric Wave Telegraphy and Telephony" very valuable. This book is worth $10.00 net, and is available thru our "Book Department" also.

IS ORDINARY WATER A CONDUCTOR?

(928) Thomas H. Hill, Washington, D. C., wishes to know:

Q. I. Is ordinary water a conductor of electricity? I don't mean chemically pure water but just ordinary drinking water as found in citiesystem.

A. I. Relative to the question as to whether or not water will conduct electricity, it is generally found that chemically pure water will not conduct electricity except when very high voltages are applied to it. This matter as we see it, boils down to the fact of its conductivity or non-conductivity as related to the presence of certain foreign chemical ingredients in the water. As you state you wish to know whether ordinary water as used for everyday drinking, cooking and other general use will conduct an electric current, we would say that it will. It may not do it very perfectly, but as an example of this condition, we might mention the following fact: When Sermen have to fight a city fire where the stream of water is liable to come in contact with a live wire of even moderate voltage, a call is generally sent to the power station to have the current shut off, as it has often happened that the firemen under these conditions have been knocked out by the shock received from the current passing along the stream of water to the brass nozzle on the hose, and thence thru their body or bodies to earth.

Diagram Showing How a Fireman Can Receive An Electric Shock Thru a Stream of Water From a Fire Hose.

Path of high tension current through fire stream.

STATIC MACHINE VOLTAGES.
(929) C. H. Denniston, Pulteney, N. Y., asks:
Q. 1. Several questions regarding the voltages of static machine sparks and the danger of shocks from these sparks.
A. 1. For every 1-inch spark 20,000 volts is usually figured, and as most small machines give 3-inch sparks, naturally the voltage is 60,000.

This potential of 60,000 volts for a 3-inch static machine spark is to be considered as the root-mean-square value, and not the maximum voltage. The maximum potential of static machines is generally computed at approximately 50,000 volts per 1-inch spark; this gives 150,000 volts maximum value for your machine. Moreover it is the maximum or peak value which you feel as a shock of any kind to the person when the discharge and wave form of the potential are of a certain proportion. The amplitude factor of the potential determines that the R. M. S. and the corresponding maximum or peak value shall be. For example, in the case of the static machine just cited, the amplitude factor can be taken as 2.5 and therefore if the 3-inch spark is taken as having a R. M. S. voltage of 60,000 volts, then 2.5 times this potential gives 150,000 volts. A similar value for maximum potentials of induction coil sparks is often used.

It has been stated that I-20 amperes pass thru the human heart is sufficient to cause death. To pass this current thru the heart you must of course have sufficient voltage this depends upon the health of the individual and the condition of the blood and nerves. A potential of 1,800 volts is used generally for electocuting criminals.

The average electrical man will tell you, that the reason why you don’t mind the shock from a spark coil or static machine is because of the lack of current—or amperage. For data on an induction coil voltage is thus been proven that at least for these cases, it is not the usual explanation—no amperage—that fails to spell fatal results, but sharpness of wave form and that it is the noscious potential effect. When the victim of the electric chair “gets his” he receives a slowly undulating wave of say 50 or 60 cycles R.M.S. potential. The current sinks in—generally it burns the heart. But when a person gets an induction coil or static machine discharge thru his body, every one, it is invariably the case that he only receives the current for a very small fraction of a second, and muscles are not affected. This theory is considered in by several high authorities in the electrical engineering field. A more full explanation is given in an article entitled “The Measurement of High Potentials” by H. W. Secor, in the August, 1913, issue of Modern Electrics.

WAVE METER TO MEASURE 12,000 METER WAVES.
(933) H. Holmberg, Bottineau, N. D., asks:
A. 1. For data on an induction coil voltage to be used with 500 m. variable condenser to measure waves 12,000 meters in length. A. 1. An induction coil for use in connection with a wave meter so that wave lengths up to 12,000 meters can be measured, when a variable capacity up to 500 m. is shunted across the inductance, will require an approximately 500 feet of littezhedh wire consisting of 10 stands of No. 38 B&.S. gauge.

The above result was derived in the following manner: Referring to the literature on Inductance and Capacity by Messrs. Secor and Cohen in the March, April and September issues of the Electrical Experimenter, we find that the inductance required is equal to 40,540,000 cm.

From the above you can see that it is very easy to calculate the inductance required.

ELECTRICAL EXPERIMENTER

Mesco Telegraph Practice Set
For Learning Telegraph Codes

The practice set comprises a regular telegraph key, without circuit breaker, a special high pitch buzzer, one call Red Seal Dry Battery, and four feet of green silk covered flexible cord.

The key and buzzer are mounted on a highly finished wood base, and three nickel plated binding posts are so connected that the set may be used for five different purposes.

List No. 342 Telegraph Practice Set, with Battery and Cord

Price $2.70

Wells, the publisher

Price does not include postage.

MESCO Combination Practice Set for Learning the Morse and Continental Visual and Audible Codes

This outfit is the only reliable instrument which will enable students to become proficient operators in the U. S. Naval Service, because it is equipped with a buzzer and auditive lamp enabling the user to receive and send the Morse code quickly.

List No. 93—Practice Set with Red Seal Battery and Cord

Price $3.60

Wells, the publisher

Price does not include postage.

Send for the New Edition of Our Catalog W28

It is pocket size, contains 260 pages, with over 1,000 illustrations, and is distributed in plants, trade schools, colleges, high schools, teachers, theory and practical telegraph material, electric toys, dry battery and telephone systems, electric clocks, burglar alarm systems, clock and watch repair, new machines, new materials, new methods, and new developments.

RADIUS AND WIRELESS.

(931) Louis Morgen Faulkner, Washington, Conn., inquires:

Q. 1. Has any research ever been conducted on the effect of radioactivity as related to the propagation of wireless waves?

A. 1. We have consulted several authorities on the subject, and find that in 1912 Professor Dieckmann of Germany conducted some tests to ascertain whether any radioactive elements were deposited upon antenna by incoming radio waves. In this connection he used the electroscope. It was shown that a slight deposit is noticeable upon the antenna, altho it might be said that the air itself contains radio-active elements.

Further, there is no record of an electro-scope ever being used for the actual reception of radio waves, and believe there is a very good field open in this direction for research work.

EXPERIMENTAL MECHANICS.

(Continued from page 106)

of the wheels on the gear centers, to give the requisite ratio of speed between spindle and screw.

In order to cut a thread below 12 pitch, a single set of the three gears is used, namely one driver on the spindle; one driven, on the screw, and one intermediate gear on the stud. It is worth remembering that a mere idler or intermediate wheel does not effect the ratio between spindle and screw speed; it is merely used to convey motion.

The size of the gear that is involved is the number of teeth, must bear the same ratio as does the screw to be cut to the lead screw of the lathe; hence we will adopt the following rule:

Take the pitch of the lead screw as the numerator of a fraction and the pitch of the screw as denominator, multiply both by 5 or 10, and the products will be the wheels required—the numerator being the spindle gear or driver, and the denominator the screw gear or driven. In order to fully appreciate this simple rule, let us take an example. Suppose we desire to cut eight threads per inch with the lead screw having five threads per inch. The thing we want to know is, what size gears will be required to obtain this thread? Applying the rule we get:

lead screw

25 spindle or driver
screw to be cut

8

5

25 

8

40 screw or driven

The gears required.

To cut a thread of screw pitch higher than 12 per inch may require for convenience of gearing or bringing the sizes within the compass of the wheels usually supplied, that a double train (four gears) be employed; this scheme is called compounding and this method is shown in Fig. 6.

In order to compound the gears, proceed with our first rule, setting forth the ratio of screw to be cut to lead screw in a simple fraction form, then assume any two other equal wheels, for second driver or driven, in the same form, and divide one driver and one driven by any convenient divisor to bring the figures within the compass of your gears. Thus applying the above rule to a particular example, of cutting a screw of 25 threads per inch, with a lead screw having four threads per inch, we have:

\[ \frac{4}{40} = \frac{x}{10} \]

\[ x = 10 \]

Assume

100

40

25

20

25

100

and we get \( \frac{4}{40} = \frac{x}{10} \); the four wheels required. Another problem; wanted to cut nineteen threads per inch with a lead screw

of four threads per inch. Here we have:

\[ \frac{4}{40} = \frac{x}{10} \]

\[ x = 40 \]

\[ \frac{10}{40} = \frac{100}{50} \]

\[ 100 \]

40

50

90

100

100

95

100

A little study on the part of the experimenter on the above will make him a master in handling the above simple rules and allow him to figure out any combination of gears both simple and compound, for cutting a thread of any desired pitch.

When adjusting the stud, take care that the gears do not go too deep in mesh, or they will bind against each other. The stud should be so adjusted that the gears all run evenly and smoothly. It makes no difference what gear is used on the stud, as it does not enter in any way into the calculation for the pitch of the thread to be cut.

If a left-hand thread is to be cut it may be necessary to use two studs as shown in Fig. 5.

All modern lathes are furnished with a key called an index plate which gives the relation of gears for cutting any desired thread. A typical index plate is shown in Fig. 7. You will note that the size of desired thread is given in the first row, while in the second the size of the spindle gear and the last the screw gear. Then to find the size of gear necessary to cut a particular thread, look for the figure corresponding to the desired thread, then opposite you will find the given size of the spindle and lead screw gears. Any size gear is placed on the change gear bracket which will properly connect the spindle and lead screw gear.

In this lesson we have considered the subject of setting the various gears necessary to cut a particular thread, while in the next lesson we shall further consider the subject of thread cutting by giving up "How to cut the thread on the work."

(To be continued.)

Stray electric currents from a railroad are supposed to cause trees on one side of a Brussels (Belgium) street to bud again and sometimes blossom after they have shed their leaves in the fall.

Let Me Send You a Valuable Electrical Outfit FREE!

This outfit consists of the same type of standard electrical tools and instruments that I have used in my work as a practical Electrician and as an Electrical Engineer.

Mail the Opportunity Coupon below and I will send you full particulars about this remarkably liberal offer explaining how you can get this standard, working electrical outfit, absolutely free. I will also tell you how you can...

Learn Electricity Under My Personal Direction By Mail

All you need is the correct, preliminary instruction that will give you a practical knowledge of electricity. That is what I can give you—practical instruction. I have condensed my 35 years of electrical experience into a thorough, easy and quick-to-learn course of home-study instruction. To master this course requires no sacrifice on your part. You don't even need to give up your present job. I taught and advised them, I can give you the same kind of personal instruction—and am willing to boost you to a better job and bigger pay just as I have helped and am helping others. Just a little determination on your part, backed on with earnest effort. That's all you need. I will then see it personally that you get just the kind of practical instruction that an electrician must have in order to succeed. The cost is small—the terms are easy.

Here Is The Opportunity

The war has called many electricians to the front. The vacancies this created must be filled. A vast number of new electrical industries of various kinds are springing up on every hand. They also are calling for trained workers. These conditions make your opportunity. Grasp it—NOW. You know that electricians do make BIG money. The yearly salaries of those who operate lighting plants, direct electrical construction, design and install dynamos, motors and electric systems, run into the thousands of dollars. Don't think that these big jobs are beyond your reach. Backed with my personal instruction you may climb steadily upwards—there will be practically no limit to your opportunities.

Unlimited Consulting Service—FREE

You can call on me for advice at any time and I will gladly furnish it—free. I will work with you for your success not only while you're my student, but as long as you are in the electrical business. I will help you in landing a job. If at any time you want to go into the electrical business on your own book I will show you how to go about it—give you pointers on how to pick out a good location, the equipment you will need, how to train men under you, how to figure on contract work and solicit business personally and by mail. In short, I will stand by to WIN.

WRITE!

This is your chance for a successful future. Don't pass it up. Act. Take the first step toward real success now. Mail the coupon or a post card for my free book—it tells all. Also get full particulars about my remarkable Free Electrical Outfit offer. No obligation on you. Act today.

A. W. WICKS, Electrical Engineer President and Director Wicks Electrical Institute 81 W. Randolph St., Dept. 313 Chicago

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.
There is a demand for salesmen right now that never
ever existed in the history of business. With your
knowledge of electricity we can quickly train you for a
good paying position as a salesman of electrical specialties.
Sales forces are depleted everywhere owing to the draft
and enlistments. Business firms are calling for Sales-
men. They must have salesmen to keep business going.
Not only in the electrical field but in all classes of busi-
ness salesmen are badly needed.

**Be a Star Salesman**

**Learn at Home in Your Spare Time**

We have trained thousands successfully for big
paying positions. No previous experience required.
Our practical text in The Art and Science of Selling
gives you the most complete instruction in salesman-
ship ever published. Let us train you to become a
star salesman—help you earn from $2,500 to $10,000
a year. Let us prove to you that this is just what
we have done for others. Let us show you how easy
it is for you to earn big money as a salesman.

**Salesmen Now Selling**

Speed up your progress toward the $10,000 class—our wonderful nine
volumes completely covering every angle of wholesale and spe-
cialty line selling will give you abso-
olute command of every factor of suc-
cessful selling. Take advantage of our Employment Service to secure
to get better paying positions—more con-
genial lines, Salary increases ranging from
so you can be trained by
experienced salesmen through our training and service—
write us and learn what we can do for you.

**FREE 80-Page Book and Proof**

Send us the coupon below and we will promptly mail you our valuable book
on the Art and Science of Selling. Learn all the facts—how you can
master salesmanship—how you can
be trained by experienced salesmen of our Members. We will also
send you a FREE 80-page book showing many
lines of business with openings for
salesmen.

**THE DYNAOTR—A NEW VACUUM TUBE.**

(Continued from page 97)

If the circuit contains inductance and capacity, as well as resistance, a similar
action takes place. As the plate comes thru the vacuum, at a rate depend-
ing on the capacity and negative resistance, and discharge thru the circuit at a rate depend-
ing on the inductance and positive resist-
ance. If the inductance is too high, the plate will receive electrons more rapidly
than they can flow thru the inductance and will charge up to the point beyond
the point at which the rate of charge and discharge are instantaneous, equal.
The inertia of the inductor makes it go backwards, and if the resistance is not too
great it will act so as to oscillate continuously. Whether the circuit will oscillate
continuously, or come to rest, depends on the relations between inductance, positive
and negative resistance and capacity.

An ordinary dynatron short-circuited by a few turns of heavy wire will give a fre-
quency of about 20,000,000 cycles per sec-

*You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.*
age means an increase in current, which may be very large if positive and negative resistance are nearly equal. For example, the maximum aperiodic voltage amplification thus far obtained with a plotron is about 15-fold, while with a phldynatron a value of 1,000-fold has been obtained. It has been shown that the dynatron will oscillate when \( Rr < \frac{L}{C} \), where \( R \) and \( r \) are the positive and negative resistance, respectively, \( L \) and \( C \) the inductance and capacity. The frequency of oscillation is approximately 

\[ 2 \pi \sqrt{\frac{L}{C}} \]

and may be given any value from 1 to 10,000,000 by changing inductance and capacity alone. It has also been shown that for low frequencies the oscillations are very nearly pure sine waves, provided \( L \) is not too great compared with \( Rr \).

Theory indicates that this should be true for all frequencies, and a search for harmonics at radio frequencies has verified the expectation.

The dynatron, therefore, satisfied all the requirements of a radio generator, and has the advantage that its generation is invariable and free from lag, and that the frequency may be given any value by changing a single inductance or capacity. Its oscillations may be controlled either by opening and closing the main circuit, or by changing any one of the four factors \( L, C, R \), and \( r \) in accordance with the condition of oscillation given above. Its efficiency is low, probably less than 50 per cent under best conditions. This is not, however, a serious limitation, except as regards the cost of power, since the tubes are capable of running very hot without deterioration. The maximum output at radio frequency of the tubes thus far constructed is about 100 watts, but no effort has been made to develop a high power tube. It is generally necessary to transform the radio energy by means of a coupled circuit.

**ELLIS HARMONIOUS REPRODUCER**

"Humanizes" any Talking Machine

You can't realize what a marvelous improvement this wonderful new reproducer makes.

It prevents that "clash" and restores the living voice whether of soprano, contralto, tenor, baritone or bass. All is now as lifelike as LIFE—even the resonance of the violin, the true bow. The tone of the flute is marvellously perfect.

Band records are reproduced with all the tone values of instruments, every overtone and undertone brought out harmoniously—without awe wrecking astringency.

The recordings of the great symphonies are revivified with all the original subtlety; re-animates in just the right volume for home enjoyment.

**This Testimonial Speaks for Thousands of Satisfied Users**

Buffalo, N. Y., April 15th, 1918

Mr. J. H. Ellis, 410 Jefferson St., Milwaukee, Wis.

My Dear Sir: Your wonderful invention should be more widely known. Your claims for it are too modest. All who have phonographs should hear your "Melodious" Reproducer, for that is its best advertisement.

Very sincerely yours,

FRANK STEGAR.

P. S. I shall at all times place the merits of your wonderful invention before the many friends and visitors, for I know that all who hear it will want you. The public must, to know more about them. Each Melodious Reproducer is a big advertisement in itself.

**Fits Any Machine**

The Ellis Melodious Reproducer plays perfectly all disc record machines, even the subtitle type of the instrumental accompaniments. No matter what make of other machine you have—either an entirely new or one that is old and worn out—You can use the Ellis Melodious Reproducer on it and enjoy real musical pleasure.

Need not discard needles, in fact any needles that is generally used will work perfectly with the Ellis Melodious Reproducer. This weight is less than four ounces, so that records wear indefinitely if care is used.

Every reproducer is fully guaranteed for 5 years. Write for circular No. B.

**High Frequency Bargains**

In taking our inventory we found over 200 Violet-Ray machines of all makes. We selected 100 of the best machines, which we thoroughly overhauled in our factory making them better than new. Many of these machines cost over $40.00.

We have placed all these instruments in two groups and are disposing of them for the ridiculously low price of $9.75 and $12.50.

**How to secure one of these machines**

Send only 50 cents to pay express charges and we shall send you one of these instruments by express for your examination. This amount will be deducted from total cost of machine. You need not accept if not satisfactory.

Send at once for we shall send the best machines out first and the quicker you send in your order, the better machine you will get.

We shall also send our beautiful booklet "Violetta" describing the many uses for the high-frequency current. Write us before purchasing any kind of Violet-Ray Machine.

**BLEADON-DUN CO.,**

11-17 S. DESPLAINES ST.

Dept. 2A

CHICAGO
The simplest method of controlling the oscillations of the dynatron is to vary the negative resistance, by means of a grid around the filament, as in the pliodynatron. It has been shown that the negative resistance of the pliodynatron is inversely proportional to grid potential. Hence, if the ratio of inductance to capacity and resistance be initially just large enough to produce oscillation (which is also the condition for producing pure sine waves), a slight decrease in grid potential will stop the oscillations.

This is exactly what is required for the radiophone, and it is easy to make pliodynatrons which have this characteristic. The connections are shown in Fig. 4. The oscillating circuit has the pliodynatron connected up as shown, and is coupled inductively to the antenna. A microphone M, coupled thru the transformer T, to the grid circuit of the pliodynatron, serves to control the amplitude of the oscillations. A battery of a few volts, between grid and filament, keeps the grid always negative with respect to the filament.

It is found that, with a proper ratio of inductance to capacity, the amplitude of the radio waves is very nearly proportional to the grid potential, and hence to the instantaneous displacement in the vocal (speech) wave. This was proved for constant grid potential by means of a hot wire ammeter in the antenna circuit, and for alternating grid potentials by impressing a sine wave on the transformer T, and observing the form of the rectified radio waves in a coupled circuit containing a kenotron rectifier and oscillograph.

Under these circumstances, it was found that speech transmitted to the microphone M, and received at a station a few miles distant suffered very little more distortion than in the ordinary wire telephone. With a small tube giving about 10 watts, it was possible to talk wirelessly 10 miles (20 km.) with good intensity and articulation. No attempt has been made to telephone greater distances, or to develop high power pliodynatrons. The maximum output of a single tube is such that it is impossible to control thus far is about 60 watts.

It has been found that a pliodynatron in series with a suitable resistance is capable of producing an aperiodic voltage amplification of 1,000-fold. To maintain this amplification requires constant batteries and continuous attention. A value of 100-fold is, however, very easy to maintain. By connecting two pliodynatrons in series a total amplification of 10,000-fold has been obtained. With this amplification it should be possible to receive radiograms on an aperiodic antenna.

[Ed. note: Those interested in this article in detail may obtain a copy of the Proceedings of the Institute of Radio Engineers, Vol. 6, No. 1, copy of which can be procured thru our Book Department.]

Television and the Telephot

(Continued from page 96)

makes use of a cathode tube, the wires 9 and 10 from the revolving mirror sender 1 being connected to wires 9 and 10 which in turn go to an electro-magnet G. Wires 11 and 12 from revolving-mirror sender 2 go to 11 and 12 which are also connected to another electro-magnet H placed at right angles to electro-magnet G. Two pencils of cathode rays is thrown upon the screen in back of the tube, and this ray is influenced by the electro-magnets H and G synchronously to revolving mirrors 1 and 2 of the sender. Consequently a picture should be traced out on the screen of the cathode tube point by point, and it is feasible that the image could be readily obtained by this means. A condenser K is also arranged in the cathode tube to steady the cathode rays, and for certain other purposes which it is not necessary to delve into in this article. This is a particularly clever invention, but we do not have any information on how showing if it has ever been tried in practice. It certainly looks more promising than any of the others, particularly as it requires only four wires.

We must also mention a certain other type of telephot which strictly speaking is not a telephot, but belongs to the ordinary sense of the word because it does not transmit pictures by electricity, but optically. It shows how a picture can be transmitted practically by means of a single light ray. This idea was patented by Mr. Alf Sinding-Larsen of Christiana, Norway. The idea is to have two mirrors vibrating at a dif-

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.
lying on the same plane and is perpen-
dicular to the axis of oscillation of mirror 2. By these means, the elements of the in-
struments are placed in succession following a continuous zig-zag line transferred to the focus of a lens 4 placed in the opening of the reflection tube 5, said lens parallelizing the rays which meet the image point. At the receiver two similar mirrors 6 and 7 oscillating synchronously with the mirrors 2 and 3 respectively, throw the train of rays emerging from the reflection tube to the eye of an observer as indicated. The synchronous vibration of the respective pairs of mirrors is ac-
complished by ingenious means outside the scope of this article. It becomes apparent from this invention that by substituting for the lenses 4 some electrical means such as a combination of selenium cell with a revolving shutter, pictures may thus be transmitted electrically without using reflection tubes such as are shown in 5.

In fact, a system of this sort was tried some years ago by the Russian inventor Savin.

Any reader interested in the foregoing patents, by sending a self-addressed envelop to the author can ascertain the numbers of these patents which have been discussed in this article. Most of these patents are very ingenious, and contain a good deal of information on television which has not so far appeared in print outside of the patent office records.

RESEARCH AND ITS IMPOR-
TANCE TO HUMAN PROGRESS.
By Dr. W. R. Whitney
(Concluded from May Issue)

make a practical success.

A SMALL electric furnace was de-

developed so arranged that the rate of rise of temperature, the maximum temperature reached and the duration of heat at any temperature was as far control and was also recorded. The desired result was ob-
tained and this work was thus finished. It gave us a certain stock of knowledge and assurance.

At that time a very similar problem was being solved one of the engineering depart-
ments. Lightening rods and other protective apparatus for protecting lines from 

lightening, were needed. Their dimensions were 60 inches and they needed to have a definite capacity. The 60 inch long and could be placed in a porcelain kiln. The necessary variations in size were therefore made so that, in any installation, the many thousands of rods were repeatedly fired and afterward tested to yield a few hun-
dred of satisfactory product. It was evi-
dent that regulation and control of tem-
perature was necessary. This was found to be impracticable in case any considerable length were to be fired at one time, as the heated mass was so great that the rods near the walls of the retort received a very different heat treatment from those near the middle and were consequently electrically different. This difficulty led to experi-
ments along the line of a heated pipe, thru which the rods could be automatically past. Some time was spent trying to make a prac-
tical furnace out of a length of ordinary iron pipe, which was so arranged as to carry electric current to be heated to the proper baking temperature. Troubles here with oxidation of the iron finally led to substitution of carbon pipes. This re-
sulted in a carbon-tube furnace, which is merely a collection of six-foot carbon pipes, embedded in coke powder to prevent combustion, and held at the ends in water-
cooled copper clamps, which introduce the electric current. By control of this cur-

USE THESE ELECTRICAL BOOKS SEVEN DAYS AT OUR EXPENSE

By merely filling in and mailing the coupon below you can get this complete set of the Cyclopaedia of Applied Electricity on trial. Pay only small shipping charges when they arrive. Use these books for seven full days before you make up your mind whether or not you wish them. If you keep them, you may pay the special advertising price in easy installments of $2.00 a month. If you don't want them, you may send them back at our expense and you won't be out a penny.

A MASSIVE ELECTRICAL LIBRARY—NOT HANDBOOKS

These seven splendid volumes contain all the knowledge you need in order to earn big money in the electrical field. They are not thin handbooks, but thick, encyclopedia-size volumes, handsomely bound in half morocco leather, gold stamped. Each one measures 7 by 10 inches, and is 2 inches thick.

This big size permits the use of large and comprehensive illustrations, plates, diagrams, etc. Over 3,000 cuts are contained in the Cyclopeda's 3,500 pages.

The completeness of the Cyclopaedia will be a revelation to you. Everything electrical is explained in plain, simple English—every technical point is made clear. Each volume is carefully cross-indexed for instant reference.

50c a Week

For this sum—an insignificant one—this wealth of electrical information is yours. But don't you have to send us a penny until you have used the books for seven days. Then, if you decide to keep them, send only $2.00 a month—50c a week—until the special advertising price of $19.80 has been paid. The regular price of these pay-raising books is $35.00.

Consulting Service Free

A year's Consulting Membership in the American Technical Society—regular price $12.00—will be included with all orders for a limited time. The advice of an entire corps of electrical experts is yours to help you in your progress—

for a whole year FREE!

Send No Money—Just the Coupon

See these books for yourself before you buy. Remem-
ber, you don't have to buy unless you are perfectly satisfied. Send for them, read the books yourself, and then decide to buy. If you 

decide to buy, I will send you $2.00 in seven days, and the balance at the rate of $2.00 a month, until $19.80 has been paid. Then you will send me a receipt showing that the set of books and the $2.00 consulting membership are mine and fully paid for. I think that I can get along without the books, I will return them after seven days, at your expense.

AMERICAN TECHNICAL SOCIETY
Dept. E-744A, Chicago, Ill., U.S.A.
ELECTRICAL EXPERIMENTER

June, 1918

WE ship you a new Oliver Typewriter-directly from the factory for five days free trial. Keep it or return it. You are our guest; use it as much as you please. Keep it for 30 days, then pay us at the rate of $3 per month. We offer you this trial without reserve, but we have sold $51, all by our new sales plan. This is the same reason for the many of the biggest concerns. Brand new; not second hand; not used. Write today for your free trial typewriter.

The Oliver Typewriter Co.
676 Olive Typewriter Bldg.
Chicago, Ill. (663)

Convert Your Bicycle Into a Motor-Cycle

We sell you the motor complete or furnish you with the finished parts from which you can build the motor yourself with few tools. We send you complete instructions with blue prints of the drawings for $.35 or full particulars for 3-cent stamp.

UNITED STATES CIVIL SERVICE EXAMINATIONS

STENOGRAPHERS AND TYPEWRITERS WANTED

MEN AND WOMEN

The United States Government is in urgent need of thousands of typewriters and stenographers and typewriters. All who pass examinations for the departments and offices at Washington, D. C., are assured of certification for appointment. It is the manifest duty of citizens with this special knowledge to use it at this time when it will be of most value to the Government. Women especially are urged to undertake this office work. Those who have not the required training are encouraged to undertake instruction in this line for a time.

Examinations for the Departmental Service, for both men and women, are held every Tuesday at 4:30 of the principal cities of the United States, and applications may be made to the Commission at Washington, D. C., at any time.

The entrance salary ranges from $1,000 to $1,200 a year. Advancement of capable employees to higher salaries is rapidly promised. Applicants must have reached their eighteenth birthday on the date of the examination.

For full information in regard to the scope and character of the examination and for application blanks go to the nearest office of the Commissioner of Education, Washington, D. C., or to the Secretary of the United States Civil Service Board of Examiners at Boston, Mass.; New York, N. Y.; Philadelphia, Pa.; Atlantic City, New Jersey; Cincinnati, Ohio; Chicago, Ill.; St. Paul, Minn.; St. Louis, Mo.; Kansas City, Kansas; Washington, Wash.; San Francisco, Cal.; Honolulu, Hawaii; or San Juan, Porto Rico.

A. McClellan, President.
U. S. Civil Service Commission,
Washington, D. C.

30 DAYS FREE TRIAL

and freight prepaid on all orders of $10.00 or more, at once for our big catalog and free samples of our products.

Mechanical improvements. Extraordinary economy. Our work is guaranteed, or you can return it and have your money refunded.

You cannot afford to buy without a trial. Our latest improvements are evidenced by our lettered Boys, id "Rider-Agent" and "Company." Write in on your work or your pay. Get our advantage and let us show you how we made the name of "RANGER".

Ranger Typewriters are made in Los Angeles, California. Every machine is perfect in every detail. A Regular lathe, not a toy.

Swing 4 inches, 12 inches between centers. 37 inches total length. Weight 1,000 lbs. with table, etc., 1,300 lbs. Weight limited to 1,200 lbs. for city use.

Mechanically Right, a regular lathe. Not a toy.

Styphon MFG. CO., Dept. C, Toledo, Ohio

F or years we have worked in the laboratory in every conceivable way to remove the objectionable gas from incandescent lamps. We carefully determined the effect of the last molecule of every gas which could possibly enter a lamp and found this gas to be argon. As a result, Dr. Langmuir discovered the hitherto unsuspected fact that a better tungsten filament is obtainable by filling the bulb with nitrogen or argon. There had been a long time when we felt we knew with certainty that the vacuum was necessary. But there were relevant things we did not know even then. New knowledge changed the looks of things. During the vacuum work I certainly lacked faith in the untaken effects of the resistance of tungsten filaments by introduction of rare oxids and other material which we hoped would remain in the filament when hot, and when there was no resistance of operator, some suggested adding traces of such oxides for the purposes of this article. It seemed a futile experiment, but the traces served the new purpose, while greater quantities had failed.

Why should we force new knowledge to come by such difficult and circuitous routes? Can we not train ourselves to be more ready for it, more open-minded for its reception and more sinned in our satisfaction with present knowledge?

We seem to live in a rapidly changing environment so far as Nature's laws are concerned. Of a truth, we ourselves and our conception of the universe and the world, and when we have once realized this much, there comes the possibility of directing our hope and expectations, our actions and experiments along as what may call a pragmatic path. This means more care and respect for the contents of the future.

Every chemist, even in his freshman days, learned the identical fact that all material advances will be made. Because he cannot always handle them in the ways of the advanced industries and research, led to the conclusion that research is closed to him. Yet so much useful pioneer work in all fields has been done with simple experimental apparatus, coupled with such equipment that it almost seems as though this was the rule. The telegraph and telephone started with a few little pieces of wire wound hand with paper insulation. The basic work on heredity was carried out by an Austrian monk with a few garden peas. The steam engine came from the kitchen fire, and wireless from the tricks of a little spark gap. There was however, the same general kind of mind behind each one of these discoveries—the mind of the inquiring thinker.

When Professor Hertz was making observations which were based on the effects of one spark gap on another at a distance, and it included that the electric waves in space, he was not trying to improve the telegraph or telephone. He was like an inquisitive child, asking what to him were interesting experiments. He was well trained to observe, but otherwise he was like a youth guided solely by the interest in the new things he was finding. When he had added to our knowledge the few simple facts which he observed, the results of trying things, he had laid the foundation for a major advance. If he had no accident, his service was unsought or unsupported thing. He had been trained by Helmholtz, and all his life he was engaged in certain universities to do pure research work and to encourage others to do it likewise. This is important.

The reason why we should most interest in this type of work is that the one who most develops the people who support it. The American manufacturers are probably wise enough to measure the effects of their labor on their specific problem, and they will more and more effectually employ men to solve them as men appear who are competent. In this way new truths will be discovered, but not enough, nor of the kind right. The discoveries in separate industries are usually those of further refinement, or improvement. The natural ex-
tensions of present known paths, the more or less obvious additions or economies, these are the studies of the industries. By industrial research as usually successfully carried on, few new fields of human endeavor are likely to be opened up.

Therefore, one in America must do all one possibly can to encourage that kind of seeking after the new possibilities in nature which may be called the fundamentals, the truths of matter. Some call this "pure scientific research." No matter what its name, it is the learning by trial about the things the Creator has put into our hands. Gradually and continually we must learn the new and ever-broadening uses. I say this merely because this has been the path by which civilization has thus far traveled most successfully.

It is harder to produce high voltage low wattage lamps as compared to lamps of equal wattage for use on low voltage circuits, which is due to the fact that thinner wires, which are used on the high voltage circuits are harder to make.

BURNT-OUT LAMP CONTEST. (Continued from page 92)

should be somewhat stronger. The negative pole is the one upon which the small gas bubbles appear, the other is the positive pole.

Figure 6 shows a match holder or match safe submitted by a gentleman residing at 911 Hancock St., Brooklyn, N. Y., who however, must remain nameless until next month, being that he forgot to sign his name to the letter. The illustration clearly shows how this match holder is made. This is sounder work for our ladies, and should prove rather an attractive idea. The main thing to remember, however, is that the sharp upper edge should be gone over with a Bunsen burner or other hot flame to take off the cut edge. Otherwise "Pa-Paw" is likely to throw it into the ash barrel the first time he cuts his fingers.

Figure 7 shows an electric distiller or still suggested by Mr. Robert Lindsay, 522 Brighton St., El Centro, Cal. The illustration in this instance also furnishes nearly all details. A cork is inserted into the top part of the burnt-out bulb and a glass tube is inserted in the cork. If the 110-volt current is turned on, the water will become hot and steam will soon be generated. Distilled water is formed in the other vessel as shown. Other liquids besides water can be used.

Caution: No moonshining now, boys!

Figure 8 shows the idea of Solly Weitzer, 119 Lewis Ave., Westmount, Quebec, Canada. It is an emergency fuse made from the remains of a burnt-out lamp bulb. It should prove quite attractive for our many bugs. It seems such a simple idea that it is surprising no one ever thought of it before, until this Lamp Contest came along. Then it went over the top with a big hoop, almost a dozen contributors duplicating this idea!

Two good ideas were submitted by Mr. Carl Knutson, 8028 Coles Ave., Chicago, Ill., and are shown in Figure 9. The first is a rain alarm, the idea being to fill part of the bulb with diluted sulfuric acid which must come below the level of the two

"Don't tell me you never had a chance!"

"Four years ago you and I worked at the same bench. We were both discontented. Remember the noon we saw the International Correspondence Schools' advertisement? That woke me up. I realized that to get ahead I needed special training, and I decided to let the I. C. S. help me. When I marked the coupon I asked you to sign with me. You said, 'Aw forget it!'"

"I made the most of my opportunity and have been climbing ever since. You had the same chance I had, but you turned it down. No, Jim, you can't expect more money until you've trained yourself to handle bigger work."

There are lots of "Jims" in the world—in stores, factories, offices, everywhere. Are you one of them? Wake up! Every time you see an I. C. S. coupon your chance is staring you in the face. Don't turn it down.

Right now over one hundred thousand men are preparing themselves for bigger jobs and better pay through I. C. S. courses.

You can join them and get in line for promotion. Mark and mail this coupon, and find out how.
protruding lead wires. It will be seen that as soon as it starts raining, the electrolyte will rise in the vessel which will establish a good connection between the two wires which in turn will cause the rain alarm to ring. The next idea shows an electrolytic interrupter. It is made by utilizing a bulb as shown \( h \), inverted and being the two lead wires ground off smooth with the glass. The two wires of the receptacle are joined together and form the positive and the negative pole of the interrupter; the negative pole goes to the lead strip screwed to the paraffined wooden cover, and bent around as shown. The vessel is filled with 5 parts of water and one part of sulfuric acid. This makes a fair electrolytic interrupter which, however, will not last very long, as the active wires soon give out, or the glass cracks due to the lead. For short experimenting it will prove satisfactory, however. It works on 110 volts in series with any spark coil. No resistance is required.

Figure 10 shows a deflagrating globe which was suggested by Mr. Thos. W. Benson, 1305 E. Carey St., Philadelphia, Pa. Such globes are used extensively in chemical experiments as frequently described in Experimental Chemistry in this magazine.

Figure 11 shows how to make a Florence style flask as well as an Erlenmeyer flask. These were suggested by Mr. Paul de Paolis, 20 William St., Geneva, N. Y. Naturally, these flasks require large bulbs and the 100 watt or larger variety of nitrogen or Tungsten lamps lend themselves admirably for this purpose. The illustrations clearly show how the flasks are made. Ideas along this line are quite profitable, being that the glass of such bulbs is usually a good grade, and the resulting flasks are not of a bad kind at all.

Figure 12 shows a chemical retort made from a 100 watt nitrogen lamp, and this idea is shown along the same lines as that shown in Fig. 11. Quite a good retort can be made from a bulb of this kind, and we are quite certain it will prove satisfactory to the chemical experimenter. This idea is suggested by Edwin J. Farmer, 621 S. Freedom, Alliance, Ohio.

(This finishes our Contest for this month, and we hope to have some new suggestions for July.)

**EXPERIMENTAL CHEMISTRY**

(Continued from page 114)

Evident from this that the molecule is of enormous size and exceedingly complex.

The oxyhemoglobin parts with its oxygen wherever it finds compounds of carbon, hydrogen, etc., ready to be oxidized, forming with them carbon dioxide and water. The products are carried back thru the veins to the lungs, whence by way of the system is in this way purified and the waste is supplied by the digestion and assimilation of food. The oxidation of food products, after assimilation, keeps up the heat of the body as really as the combustion of carbon or sulfur liberates heat. The average temperature in man is 37 deg. C. (98.6 deg. F.). Any excess of heat produces perspiration or is changed into other forms of energy. The maintenance of temperature is nearly a fixed thing, and the health and life, but in disease the temperature of the body deviates to some extent from the normal. In Asiatic cholera it is sometimes as low as 25-26 deg. C. (77-79 deg. F.), while in pneumonia it may rise to over 41 deg. C. (106-107. deg. F.). Considerably higher temperature than these have been noted; but if this condition is continued the blood corpuscles are killed and the person dies.
Deoxidation in Plants

Since carbon dioxide is so constantly poured into the atmosphere, why is there not more carbon dioxide and less free oxygen in the air to-day than a thousand years ago? The answer may be found in the growth of vegetation. In the leaf of every plant are thousands of little "chemical laboratories," in which the tree often has access of foliage surface exposed to sunlight and air; carbon dioxide, diffused in small quantities in the air, passes into the leaf, mainly from the under surface of the stomata, or little mouths. (See vertical section of leaf, Fig. 19.) Within the leaf, probably in the green phloemphlary grain, it is decomposed by the radiant energy of the sun. The reaction supposed to take place is:

\[ 6CO_2 + 6H_2O = C_6H_{12}O_6 + 6O_2 \]

Oxygen is given back to the air; starch \((C_6H_{12}O_6)\) is retained in the leaf and is transformed into sugar and cellulose, the latter of which constitutes the fiber of the wood and which has practically the same symbol as starch or sugar, namely, \(C_6H_{12}O_6\), or a multiple of it. Carbon dioxide contributes to the growth of plants. Oxygen, to that of animals, and the constituents of the water produced little from one organism to another. The compensation of nature is here well shown. Plants feed upon what animals discard, transforming it into matter of the same nature as the latter, while animals prepare food for plants. Practically all the carbon in plants comes from the carbon dioxide in the atmosphere. Animals obtain their supply of carbon from plants. The utility of the small percentage of carbon dioxide in the air is thus seen.

**Uses.**

Carbonic acid gas uses for making soda-water, and as a basis of mineral waters and effervescent drinks of all sorts. It is also used in bread making (causing the dough to rise), and is employed very extensively in alkaline manufacture, for example, in sodium carbonate. In chemical fire engines sulfuric acid is in one tank and is let into another tank containing sodium carbonate solution, thus rapidly liberating carbon dioxide, which is forced on to the fire in its early stages. Carbon dioxide is also used for refrigeration.

**Carbon Monoxid. History**

Lassone first discovered this gas about 1776. Priestley obtained it and named it "Phlogisticated water," about 20 years later Lassone. Lavoisier supposed it to be hydric acid in solution, in 1808, proved it an oxide of carbon.

**Names:** Carbon monoxid; carbon prooxid; carbonic acid.

**Occurrence.**

Probably the gas carbon monoxide does not occur naturally anywhere, except as a product of combustion, of coal with an incomplete supply of air, and in furnaces under like conditions. It may be easily recognized in the combustion of anthracite coal by its peculiar blue flame. Almost identical with this formation of it, is the one obtained by passing carbon dioxide over red-hot charcoal.

\[ CO_2 + C = 2CO \]

**Preparation.**

One way of producing this gas is to act upon oxalic acid \((H_2C_2O_4)\) with sulfuric acid and heat. It will be seen that oxalic acid, which is a solid, consists of \(H_2\), \(C\), and \(O\), and in the exact proportion to form water \(H_2O\), carbon dioxide \(CO_2\) and carbon monoxide \(CO\). Heat alone will break up the acid into these constituents, but sulfuric acid acts in the operation and also absorbs the water, leaving the two gases, carbon dioxide and carbon monoxide, completely intermingled. Remembering the affinity which carbon dioxide has for soluble hydrosides, we can separate it by passing the mixture over sodium hydroxide, or of potassium, or of calcium hydroxide.

\[ CO_2 + 2NaOH = Na_2CO_3 + H_2O + CO \]

The carbon monoxid, being insoluble in water, can be collected like hydrogen.

The gas can also be prepared by the action of sulfuric acid on formic acid or potassium ferrocyanide \((KFe(CN)_6)\), or by heating certain oxides, as zinc oxide or carbon dioxide, with sodium carbonate.

\[ HCO_3 + Na_2CO_3 = NaHCO_3 + CO_2 + H_2O \]

**The economical method and the one that will yield the gas rapidly, is that involving the heating of finely powdered potassium ferrocyanide with eight or ten times its weight of strong sulfuric acid, which reaction takes place according to the second equation above.**

As soon as the reaction commences the heat must be removed and the vessel cooled, if necessary, in order to prevent too rapid evolution of the gas. The water required in the above reaction is derived from the water of crystallization of the potassium ferrocyanide and from the small quantity in the commercial sulfuric acid.

**Properties.**

(Physical): It is a colorless gas. It is very slightly soluble in water. It is very poisonous, one part per cent having produced death. It liquefies at 140 deg., 36 atmospheres, and boils at -190 deg. It solidifies at -190 deg. (Chemical): It unites with chlorine to form carbonyl chloride \((COCI_2)\). It combines with the hemoglobin of the blood to form carbon monoxid hemoglobin, a stronger poison than any of the other poisoning gases, hence oxygen does not displace it and it rapidly poisons. Its poisonous effects are almost instantaneous, judging from deaths resulting from inhaling water gas.

It is a non-supporter of ordinary combustion, but red-hot carbon rob carbon dioxide of half its oxygen to form carbon monoxid in the presence of no free oxygen.

**Uses.**

Carbon monoxid is a diluent in water gas and a reducing agent in ore reductions, particularly iron. As a constituent of illuminating gas, it displaces certain poisonous gases like phosgene and other animals.

The formation of CO and CO₂ in a coal stove:

The fact that CO is formed with abundance of oxygen, and CO₂ with a limited amount, is well shown in a coal fire. (See Fig. 20.) By having plenty of oxygen enter the draught, and carbon dioxide is first formed at B.

**\[ C + 2O = CO_2 \]**

But as this rises to the middle of the hot coal, where oxygen is wanting, it gives half its oxygen to the carbon and becomes reduced to carbon monoxid.

**\[ CO + C = 2CO \]**

Here, carbon acts as a reducer, CO₂ as the oxidizer. CO as reduction product. Reaching the surface of the coke, where there is plenty of oxygen, the CO becomes CO₂, burning with a blue flame.

**\[ CO + O₂ = CO_2 \]**

The danger of having the back draft A closed when the stove door is open arises from the unburned CO being forced into the room, to be breathed by the occupants.
AMERICA NEEDS
YOUR IDEAS

Submarines, torpedoes, flying machines, machine guns, immense howitzers, the British "tanks," and an untold number of other products of American brains, are dominant factors in the Great War. We are using every means of "ingenuity and victory." Uncle Sam—the whole civilized world—is seeking ideas that will aid in the fight. Can't you help with even one of thousands of simple things that will win recognition—perhaps fortune for you?

You incur no obligation by writing me. My advice nothing. I make no charge for an opinion as to patentability of your idea. If my opinion is favorable I will back it up by a Guarantee Contract which protects you fully. If you want to sell your invention, I will help you, and advertise it, free of charge, in "INVENTION AND MANUFACTURING."

A simple request will bring to you at once, my free booklet:—"SUCCESSFUL PATENTS," a 72 page guide telling how to proceed, gives references, etc.; "TEPPING STONES" tells the truth about prices of inventions, gives hundreds of hints of inventions, etc.; "PATENT BUYERS." Publishes over 400 requests of manufacturers who want ONS PATENTS, together with ideas they wish; "PATENT PRO-

EVERY INVENTOR should have this book "PATENTS AND PATENT RIGHTS." It is chock full of ideas and practical advice, telling you how to invent, and how to sell. Write for your copy today. IT IS FREE.
The best source for patents upon sound inventions of all kinds. Can you help supply the desires of manufacturers? Our service is individual, prompt and efficient.
H. S. HILL, 154 Mechanics Bldg, Washington, D.C.

AUTOMATIC LIGHTING SYSTEM.
(228) John R. Fell, Jr., Parkersburg, W. Va., sends us an idea of an automatic light scheme, the purpose of the arrangement being that when one lamp breaks or burns out the circuit is broken; this releases the armature of an electro-magnet which closes a contact, and in turn lights another light. Our advice is asked.

A: This is a very ancient idea, and has been used as far back as 1870, when the first automatic arc lamps were invented by Jablkoichoff of Paris. It is also used at present on certain automobiles to give warning when the rear light should break or burn out. Years ago, the Editor had a system of this kind on the market worked on the same principle which he termed the "Tell-Tale Tail Lamp." This was on the market in 1906.

INSULATOR.
(229) H. H., Glace Bay, Nova Scotia, Can., has submitted drawings of a certain insulator, whereby the wire can be attached to the insulator without any additional means. Our advice is asked.

A: This seems to be a very good idea, except that if the insulator is made in porcelain there would be trouble with the two screw parts, as porcelain does not lend
Invent Something

Your Ideas May Bring Wealth. If patented, always a demand for valuable inventions.

Über a patent can be obtained on the idea.

Alvin Messall, Colorado Springs, Colo., submits drawings and designs whereby a fuse is incorporated right into the lamp socket, which idea he thinks would make it possible for anyone to see just exactly where the fuse had blown. A. This is not a practical idea to our mind, as it would necessitate too many fuses which are not at all necessary. We do not think that anyone would wish to adopt a plan of this kind.

A. Roy N. Bick, Colorado Springs, Colo., submits an idea of a war aeroplane using a new form of propulsion. The idea is to use a boiler, and instead of water he proposes alcohol. This is one of the main features of the scheme. A. We are afraid that such an aeroplane, while it might leave the ground, would be far too heavy, and the idea of using alcohol instead of water would probably be looked upon with disfavor by the average aviator, at least at the present time. We do not believe that such a boiler has been far enough advanced to be used on an aeroplane.

Automatic Telegraph Transmitter.

Marius Zaayer, Boston, Mass., has patented a telegraph transmitter in which, by using a condenser, the instrument is not only very useful for a commercial instrument, but for a commercial instrument, as such was described in our October, 1916, issue. Our correspondent also desires all possible information about automatic keyboard transmitters of this kind. A. We respectfully refer him to a patent...
WIRELESS SALE

On April 6th of last year, when war was declared, we had made preparations to give our patrons wonderful service and had acquired an enormous stock of our most popular wireless instruments below mentioned. We desire to reduce this stock to the extent of $5,000, still retaining a big reserve when the wireless station is not in demand. We have just slaughtered the prices. Remember that during the past year wireless keys and everything electrical has increased tremendously and it is an absolute certainty that wireless instruments manufactured when the war is over will sell at greatly increased prices. The demand will be so terrific that thousands will have to wait months for their instruments. Many are now getting their stations ready. This is your opportunity. When this stock is adequately reduced no further orders will be accepted and remittance will be returned.

GAS GUN.

(233) H. W. Seeley, Bridgeport, Conn., claims that he has experimented for some time and now he terms a "Gas Gun." The cannon is supposed to be of brass or steel and is to be fired with gas. Certain other information is given as to how to operate it, as well as other various details. He also claims that with such a gun he has hurled objects with considerable force for fairly long distances, but he admits that it is not a gun of a small size. Our advice is asked.

A. In view of the fact that late advices from Germany thru Swiss sources mention that the famous 74-mile gun which the Germans used in shelling Paris are supposed to be using gas, our correspondent's idea seems feasible. How practical such a device is, is not known to us. Until the German came along no one ever spoke of gas guns, but there is a good chance that there may be a future of this kind. We would advise our correspondent to proceed cautiously, and have a thorough patent search made before applying for patent.

AUDION.

(234) E. F. Johnson, Waseca, Minn., thinks he can construct a step-down transformer in connection with an Audion. He shows several schemes to be used in connection with the idea.

A. We are of opinion to use A. C. current in connection with such a sensitive device as an Audion, as we are almost certain that a loud hum will result when the transformer is doubled upon. If the same can be overcome entirely to make the operation of the instrument suitable. Because the arrangement is used in connection with the transformer, the constantly changing potential of the line is certain to interfere with the operation of the Audion. Everytime somebody down the line turns on a number of lights there is a disturbance along the entire circuit, which will certainly manifest itself in the Audion.

AN ELECTRIC AEROPLANE SHOOTING GALLERY.

(Continued from page 77) pathway, the target being preferably in the form of a miniature aeroplane as here illustrated.

In the front portion of the gallery there is arranged a shooter's stand and in the rear a targeting stand adapted to be shot at by the shooters or gunmen standing on the stand. The shooter's stand is preferably in the form of an aeroplane suspended in mid-air and adapted to rock from side to side. The lower wing of the stand forms a floor for the shooters to stand on and a target to face to the end portions of this floor so that the shooters can board the "aeroplane" readily.

Various mechanical means may be employed to make the aeroplane stand and for impinging a-rocking thereto, for instance, as shown in the drawings, the floor on which the marksmen stand is hinged at its ends on springs or on rods, connected at their upper ends with the cranks attached to crank shafts journalized in suitable bearings arranged on brackets and attached to an overhead beam extending along the ceiling of the gallery. The crank shafts are provided with bevel gear wheels meshing with a second set of bevel gear wheels secured on a shaft driven by an electric motor. When the motor is running then a rotary motion is transmitted by the gearing described to the shaft and cranks, whereby a rotary motion is given the links and imparting a side ways rocking motion to the shooter's stand, as is readily understood by reference to the illustration.

The rear of the suspended stand is provided with propellers and a spinning wheel and sprocket chain mechanism from an electric motor mounted on the floor, and the propellers are preferably included in a wire netting protector. When the motor is running a very realistic aeroplane effect to the shooters standing on the floor as well as to the onlookers in front of the shooting gallery.

Each of the miniature aeroplane targets is provided on top with an eye detachably engaging the return bent end of a holder, in the form of a rod provided with a flanged wheel, traveling in an endless slot formed in the target background extending across the gallery in the rear of the targets. The rear end of each holder is attached to an endless traveling sprocket chain passing around a series of sprocket wheels located in such a position as to guide the sprocket chain along the slot as is readily understood. A suitable electric driving motor is connected with one of the sprocket chain wheels traveling motion to the chain and targets.

As the marksman hit the aeroplane targets they can thus be easily replaced by an attendant located at one side of the target stand, as they are shown hooked on any of the slow moving shafts.

To give a truly realistic effect to the whole affair the inventor mentions that a moving cloud machine is provided in the gallery, that is attached to a target board, so that the resemblance to the "real thing" will be greatly heightened thereby. Also it is not necessary to have the shooting gallery in the open; it can be very effectively placed in an enclosure so that a moving earth panorama can be projected on the floor between the plane and the target.

A 100-MILE ELECTRO-MAGNETIC GUN.

(Continued from page 81) has a possible range of 90 to 100 miles when properly designed and elevated to a maximum range of 45 degrees. The principle of the electro-magnetic gun is best understood by reference to the line drawing here shown. Prof. Christian Birke- land, inventor of the gigantic solenoid gun mentioned, his patent being granted January 13, 1914, tried out a simple experiment to prove that his design was feasible and practical. This experiment was made with a single magnetic field weighing about 24 lbs., and having the dimensions given in sketch. Here is what he says:

"With a current of 200 amperes sent thru the solenoid, the iron rod was sucked in and propelled with a magnetic pull of 170 lbs. The heat generated in the coil was not over 30 degrees Fahrenheit. It is evident that this design is a great improvement upon the original design of the solenoid gun, the current required being only one-tenth of the original. The equipment of the gun is very simple and the solenoid gun is very much cheaper than the original design. It is evident that there is a great future for the electro-magnetic gun and that it will be one of the most powerful and efficient weapons in the hands of the army in the future."

$720.00 for $15.00!!

Size of machine \(19\frac{3}{4} \times 8\frac{1}{2} \times 8\frac{1}{4}\). Net weight 18 lbs.

TAPE RECORDER AND PERFORATING MACHINE

This is a standard commercial, large size, perforating, telegraph recorder. It is exactly the same machine as used by the Western Union and Commercial Telegraph Companies in their main offices. This machine requires a double contact (back stop) telegraph key and a few batteries. Pressing the key operates in turn the two sets of powerful electro-magnets, which on their part operate the two ratchet wheels. These then operate two plungers which punch the holes in the tape. By sending Morse code, the holes are punched in a certain manner. Then, by feeding the tape back thru the machine and by arranging two brass contact fingers, the tape will spell out dots and dashes by means of a buzzer.

This machine has a truly wonderful spring motor. It is absolutely silent and has a centrifugal regulator speed-adjuster and stop arrangement. At the highest speed the motor runs 15 minutes, at the slowest speed 65 minutes continuously. Over all dimensions of machine are \(18\frac{3}{4} \times 8\frac{1}{2} \times 8\frac{1}{4}\). Diameter of holes punched \(1/16\). The width of paper tape is \(1/8\). Aluminum reel \(6\frac{1}{2}\) dia. The magnets measure \(1\frac{1}{2}\) dia. and are \(1\frac{1}{4}\) high. The net weight of the machine is 18 lbs. Our line, shows machine with cover removed to show motor. The small insert shows the beautiful tandem electro-magnet arrangement, the ratchet wheels and perforating equipment. All wood work is solid mahogany.

USES: What you can do with this beautiful machine:
1ST—USE IT AS A PERFORATING MACHINE
2ND—AS A REGULAR MORSE REGISTER
3RD—AS A SPECIAL REGISTER
4TH—AS A TELEGRAPHPHONE

We furnish Blue Prints and full directions to make all the above apparatus using the recorder. We also furnish 3 paper feed tapes, standard size.

A similar machine is listed at $100.00 in the catalog of the Western Electric Co. We bought these machines cheap thru auction, hence the ridiculously low price. AND EVERY MACHINE IS BRAND NEW, has never been used, and is in perfect working order—or money back. IT COSTS ITS ORIGINAL OWNERS $70.00.

We have not a very large quantity of these machines on hand. This is your one chance—you will never see such a bargain as long as you live—we are quite certain of it.

The size of the machine being \(18\frac{3}{4} \times 8\frac{1}{2} \times 8\frac{1}{4}\), the net weight 18 lbs. (shipping weight 20 lbs.), make it necessary to ship by express or freight. We guarantee immediate shipment within 24 hours after receipt of an order.

Price as described:

- complete: $15.00

“ELECTRO” LOUD-TALKER

We present herewith two little instruments for which we have had a long and persistent demand.

This outfit has been gotten up solely for the Experimenters and for this reason we are selling it “Knocked Down.” In other words, the instruments come all ready for you to assemble, all the parts, wires, nuts, washers, etc., being threaded. This is the only way in which we can afford to make such an instrument. The driver, the outfit can be rendered self together in less than twenty minutes.

The most important point is that the telephone receiver speed greatly exceeds the speed of the Electro. Therefore, not need to wind his own own.

The outfit when assembled comprises a highly sensitive CARBON BALL MICROPHONE with carbon discriminators of exactly the same type as used with our $15.00 Detectors. (See our Cat. No. 10.)

The “Back Plate” which holds the carbon balls has five cup shaped polished depressions, each accommodated by a separate carbon ball. The carbon balls are made of the special carbon balls furnished in a bottle.

The receiver is our No. 1820 with the difference that the magnet was taken out. For this reason that the function of

A 100-MILE ELECTRO-MAGNETIC GUN.

(Continued from page 132)

the small line drawings herewith, showing a simple three-coil electro-magnetic gun, and undoubtedly the reader will then be able to grasp, with the aid of the following explanatory remarks, about how the various inventors of the electro-magnetic guns intend hurling their projectiles at the enemy with astonishing rapidity and accuracy.

For the sake of simplicity, we may consider that but three electro-magnetic coils are in use as at 1, 2 and 3 along the gun barrel. It may be said that invariably such a gun barrel should have an inner lining of brass or bronze, so that the projectile which is usually made of a magnetic material (such as iron or steel), will not bind within the barrel. The barrel proper can be made of iron properly divided, but an all-brass barrel is common. Now consider that the three magnet coils, 1, 2 and 3, are connected up to a switch as shown. If, then, an iron projectile is placed in the position A, and the current caused to flow thru the coil 1, the electro-magnetic field of force set up within the gun barrel will tend to pull the projectile forward in the direction of the coil 1. This should be mentioned before going further that the iron barrel (if used) of the cannon or gun is divided up into several distinct sections so as to form the gun as a magnetic pull on the projectile at each new impulse.

When the projectile has reached the position of coil 1 the control switch is moved so as to cut out coil 1 and to connect coil 2 into circuit. If this is done quickly the projectile will have been sucked forward on a line with coil 2. The operation is again repeated and the switch is moved so that coil 3 will be put into the circuit and coils 1 and 2 opened. Thus the projectile will again be sucked forward to section 3, and at the instant it reaches the center of the final coil the current is cut off and the momentum acquired by the projectile is relied upon to carry it on and out of the muzzle of the gun at B.

In one of the illustrations there is shown a probable development of a large electro-magnetic field gun mounted on a massive iron frame-work fitted with large caterpillar wheels, as observed, so that it is mobile enough to be quickly hauled from one place to another on the battlefield or for siege purposes. When used for portable requirements it will invariably be necessary, if such guns are ever adopted, to provide a complete portable electric generating plant as is shown in the picture. This would comprise a powerful gasolene engine direct connected to a suitable electric dynamo.

Some idea of the possible size of such guns may be obtained when it is stated that one of the best designs ever worked out on this principle, and due to Prof. Birkenhead, has a barrel 90 feet in length. The projectiles used in this gun would be about 2 feet long and have a diameter of 19 inches. Also to gain the maximum magnetic pull by this arrangement it is recommended that the projectile be wound with coils of wire so as to be electro-magnetically reactive in conjunction with the regular magnetic disc coils placed along the barrel of the gun. As perceived, the gun will be of such a size and weight that the shells would have to leave the gun barrel with a velocity of 4,000 ft. per second. In order to facilitate the passage of the projectile thru the barrel of the gun with the least friction we strongly suggest that suitable lubrication be provided by means of grease or oil cups placed along the barrel at intervals; these may be observed in our illustration.

It must be remembered that these guns would not heat to any appreciable extent and not at all compared to the heat produced in the modern high powered guns using explosive charges of powder. Due to this and other advantages such a gun as this can fire a great number of larger caliber shells per minute, possibly
fifty to seventy-five shells in one minute. It will be seen from the foregoing that such a discharge of 19-inch-two-ton shells, each of which contains a 1,000 lb. high explosive powder charge, would serve to quickly rout the enemy, no matter how well he might be entrenched or concealed behind fortified embankments. A rain of such monster shells would batter down almost any fortification whether natural or built by man.

A method is suggested in the illustration of this electromagnetic gun whereby a constant supply of shells for rapid firing can be always maintained before the open breach of the gun. The shells might be hoisted by means of a gasoline engine and run on the platform at the left and then allowed to slide by gravity down the inclined chute. As fast as one of the shells is sucked into the breach of the gun barrel it is followed by another right after it successively. It is easily possible to have means of firing the shells as far apart, in respect to time, as is deemed advisable, of course. The electric current supplied thru the coils along the gun barrel can be controlled thru a suitable switch by the man aiming the gun and who may be located alongside of the breach of the monster as indicated in our illustration.

The second large electromagnetic gun illustrated in the line drawing is a design suggested by Mr. Paul E. Kenny, a New York electrical engineer. This basic design principle is similar to Prof. Birkeland's, namely, to apply a very large electric current to the magnet coils surrounding the gun barrel for a fraction of a second, or in other words to create an enormous magnetic suction to act on the projectile before the magnet coils have had time to heat up, time being one of the factors governing the heating effect in any case. The shorter the time the current is on, the less the amount of heat produced. Thus does it become possible to overload the coils on the magnetic gun 10 to 12 times their normal carrying capacity, as pointed out before, to thus realize a corresponding increase in the strength of magnetic field produced.

Mr. Kenny says that he offered it to the United States Government in 1908, and proposed that a shell nineteen inches, from New York to Philadelphia, to prove what it could do, but his offer was refused, on the ground it was too big.
The making of an Electrical Man.

(Continued from page 88)

in uplifting environment and makes the right kind of men out of them, instead of the usual sort of school graduate.

All branches of electricity are taught and every grade is provided. Whatever a young man's knowledge, ability or previous education, there is the proper starting place for him at this school. There are no specific requirements other than the ambition to succeed; and each student is advanced as his ability warrants.

The courses taught are: Complete Electrical Course, D. C. and A. C. Electrical Engineering, 2 to 2 ½ years. Electrical Engineering, in 3 years (probably the only electrical engineering in 3-year course given, others requiring 4 years). In addition there are the following special Six-Month Courses: Electric Trouble and Lineman; Electric Meterman; Electric Motor Repairman; Telephone Trouble and Repairman; Draftsman.

The school is empowered, under the Laws of the State of Wisconsin, to give Bachelor, Master Science and Electrical Engineer Degrees to graduates, which substantiates its standing as an educational institution and insures its recognized strength in the field of electrical industry.

Moving Pictures That Really Talk.

(Continued from page 88)

from a powerful arc lamp is projected thru the galvanometer and in a magnified form throws the shadow of the moving wire onto the steadily moving film behind a narrow horizontal slot.

The film passes thru the camera at the rate of 20 images per second, while its movement thru the sound recorder is continuous, for the reason that it is not feasible to reproduce images and sound records side by side. The string galvanometer has received much thought and attention as to its design as it really is the heart of the invention. In the earlier form the inventor used a single wire which made a record similar to the small piece of film shown herewith. In his more recent form use is made of two wires. When current passes thru them they operate in opposite directions, so that a double row of sound waves are recorded with the points of the peaks facing each other.

In projecting the film with the sound waves on the same it has been found that these various dark and light portions of these air apparatus, is a remarkable sensitive cell, which in turn will operate a suitable form of acoustic receiver or reproducer.

The film in showing passes thru the projector proper at a slight increase of speed (the regulation film runs at 16 images per second, while Mr. Laste's film runs at 20) and then thru the sound reproducer.

A powerful, sharply focused beam of light is projected thru the sound-bearing section of the film and so on a selenium cell. In the present apparatus a remarkably sensitive cell of circular form with a range of resistance from 1,000 to 100,000 ohms is employed.

A sensitive relay is used in circuit with the selenium cell, which in turn operates a speaking horn of special design which the inventor cannot disclose at present. The horn is totally different and a radical departure from any telephonic reproducer now used, in that it operates on a valve principle similar to the human throat, thereby eliminating the metallic sounds usual with telephone apparatus. The sounds are amplified with a specially designed compact air apparatus, making it possible to hear clearly in the large auditorium or theater.
How to Avoid Electric Shocks.

(Continued from page 82)

may lie on a sidewalk or street in a very hazardous position.

If a person has been caught by a live wire and conditions demand that you try to relieve them, the first thing to consider is to eliminate or remove the wire from the body, if it is coiled about the victim, by means of a dry stick of wood several feet in length. Observers have been recorded that such a rescue was made by means of a dry coat or other cloth, if several thicknesses of the cloth are used, when a person may in an emergency grasp such a live wire, if it is not carrying too high a voltage, say not over 3,000 volts, and pull it from the victim's body. It is possible a person attempting such a maneuver should in every case endeavor to insulate himself from the ground by all means, such as by using a piece of dry wood, a rubber, or a coat, or several thicknesses of heavy dry paper. Rubber gloves, such as lineman use or even heavy leather gloves, will often serve to prevent a shock from a live wire, their body is at a similar potential, and therefore, the would-be rescuer should not touch the victim's body or clothing without taking the aforementioned precautions.

Persons have been fatally shocked when using a telephone after an artist or laborer has portrayed in Fig. 6. Such a shock may be received due to several reasons among which are the following: A severe storm may cause a strong lightning surge to be set up in the telephone circuit, and the current due to this surge may give rise to a dangerous potential being generated at a suitable telephone apparatus momentarily, or just at the moment when a person might remove the receiver from the hook and attempt to use the instrument. Another cause for receiving fatal shocks of this nature, and which are on record, is due to the fact that in rainy weather, particularly, it is a case now and then that the heavy wind of a storm may blow down a high potential feed wire, so that it crosses a telephone wire, and the telephone apparatus would be charged with a dangerously high voltage current as becomes evident, and a person using a telephone instrument might immediately become the victim of such circumstances.

The women folks are gradually becoming more attached to the excellent facilities afforded by the use of electric toilet appliances, etc., and in Fig. 7 we have illustrated a condition which might occur, in which a lady would receive a shock thru her body by placing her feet on a radiator or heating register, when an electric curling iron is in use. Ordinarily, of course, these electrical appliances are thoroughly insulated when manufactured and rarely break down. It is the exception and not the rule we wish to point out, that electrical appliances break down so that the outer covering or metal shell of the apparatus becomes what is known as a "live," and the condition is that the ground is allowed to come down between the electrical heating or other circuit inside the apparatus, and allow the apparatus to leak across the metal enclosing shell.

The apparatus in this condition is liable to give users thereof a surprising shock if their bare bodies come too near the apparatus, or are forced to the apparatus for a moment to get in contact with any grounded piping.

Boys will be boys, but we cannot too strongly caution the young dare-devils among the rising generation not to throw a wire over trolley lines! The writer can remember when he had this same big idea, but when he was ten years of age; it is invariably the case for a youth of this age to do unusual things. "Always something spectacular" is their unvarying motto. This has happened in the case of a boy, who, having met his doom thru just such tactics as this, viz., by throwing a wire or even a wet string over a trolley line, has done exactly what does not stand on the trolley track (thru which the current on trolley systems is returned to the power house and which completes the circuit from the pole line in any case), but put the ground alongside the track, he is quite likely to receive such a severe shock that it may prove fatal. Trolley systems usually employ a current of 50 to 600 volts potential, and a shock from this current or even a part of it may prove fatal. A person struck to a shock of this kind due to a falling trolley wire, or by their coming in contact with a fallen trolley conductor. (See Fig. 8.)

Illustration Fig. 9 shows how the "live" third rail is applied in numerous electrified railroad systems, and which is also found on many city electric traction systems such as in the subways and on elevated roads. There are a few pertinent facts concerning third rails which everybody should study next to the Bible, and these are the following:

Remember first that a current of 600 volts potential and in some cases a higher potential is always present between the third rail and either one of the regular car rails lying adjacent to it, and therefore never step on a third rail under any condition. If you do, you will possibly receive a full 600-volt shock thru your lower extremities, the current passing from the third rail up through the leg thru the lower abdominal organs, with a chance of reaching the victim's heart and killing him, and out thru the other leg to the car rail. You do not have to stand on a third rail and a car rail to receive a very unpleasant or dangerous shock, for if you happen to touch the third rail with one foot, with the other foot on a wet wooden tie you are liable to receive a thoroughly sufficient leak or short circuit in this way also.

In this connection, we might mention a wire which was few years ago between two men who were standing on an elevated railroad platform in New York City, and which is more scientific third rail of which we do not recommend anyone to try, for it is always fraught with danger. One of the men let the other that he could walk on the third rail without receiving any shock. His friend took up the bet, and true to his promise the first better proceeded to win the bet as follows: He jumped from the station platform down to the road-bed from the road-bed he jumped on the third rail, and then a third step along it, he jumped off the third rail with both feet simultaneously back on to the roadbed, and then climbed up to the platform and collected his reward. He never received any shock of course, whatever, owing to the fact that when he stood on the third rail, he did so with two feet and not with one foot touching an exposed charged electrode or body. This also explains how a bird can alight on high voltage lines when people frequently are amazed at. The answer is simple, as in the above case. This is so for the reason that to receive a shock you must have both feet in contact with the positive and negative sides of a circuit, or in other words, you have got to complete a circuit charged at a certain potential to the op-

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.

In Fig. 10 there is shown a very common way in which persons working in factories and particularly in foundries and similar shops provided with earth floors receive shocks, as under these conditions they will frequently and carelessly touch the "live" blade of a switch in starting up a motor, or they may allow their fingers to get in contact with "live" metal parts on motor starting boxes, speed controllers, etc. Under this condition they will receive a shock which sometimes proves fatal. The current passing from the live metal part of the starting box, which they happen to touch, down thru the body to the earth on which they are standing, and thence back to the opposite side of the circuit thru the usual ground of such systems. The rule to follow here is—to always stand on a piece of dry board, a wooden box or several thicknesses of dry paper; further they should always be careful not to touch any "live" parts of the switch or starting box.

Electricians and others often receive disagreeable shocks while repairing dynamos and other machinery as well as electric light sockets when they sometimes have to stand on an earth floor as in foundries and in other locations, when the danger of receiving such a shock may be readily eliminated by standing on a piece of dry board or several thicknesses of dry paper.

The writer recollects a very peculiar case when an electrician attempted to repair a live electric light socket in a fish market—but his fish hook was also shocked for. The electrician had to climb up on something in order to reach the socket, and grabbed hold of several small convenient boxes which he placed on top of the other, and these he placed in turn on a large marble slab which was used in the fish market for cleaning fish. Well here's what happened in a few words, and a more surprised electrician you never saw. The boxes looked thoroly dry, and they were dry to all appearances, but when he mounted the third box and touched one side of the socket connection he got a severe jolt, which of course at once told him that his body was earthed but how? The answer was soon evident on a little reflection. The marble slab, owing to frequent usage, was thoroly impregnated with salt brine as well as the boxes. The problem was solved by going outside on the street and purchasing a couple of newspapers for two cents. Going back to the job on hand, the electrician folded the newspapers several times and placed them on top of the uppermost box. No more shocks were received after thus solving the problem.

It has often happened that firemen have been severely shocked or killed while fighting fires, when a stream of water happened to come in contact with high tension electric light wires. The illustration hereewith, Fig. 12, shows how a fireman, or in fact any person using a hose such as a garden hose for instance, may protect themselves against such a contingency by touching the brass nozzle of the hose. They should be careful to keep hold of the rubber hose which must not be wet and which will act as an insulator, but if they grasp the brass nozzle and in case the stream of water touches the electric light wires on the house, etc., a current is liable to pass along the stream of water, and if it touches the nozzle it may pass thru his body to earth. It frequently happens that high potential feed wires pass in close proximity to houses, carrying as high as 2,500 to 5,000 volts, and thus it is possible for a person fighting a conflagration under the opposite side of that circuit charged at an opposite potential.
ELECTRICAL EXPERIMENTER

POWERFUL ELECTRO-MAGNETS
—WHAT THEY CAN LIFT.

(Continued from page 89)

at 40 to 60 miles per hour, and to nitify them out of the water before they can hit the vessel's hull and damage it. The tendency in the first place is backed by a 200 H. P. comprest air engine, and, traveling at express-train speed, its momentum can readily be imagined. Such a powerful magnetic force would not deflect a modern automobile torpedo to any practical degree, by any known application of the laws of attraction, as is the firm opinion of the Naval experts.

With these large magnets the attractive force on a steel plate is not as great as the largest magnets we expect, on account of the small cross section in the plate available for the magnetic flux. Many schemes are presented to us for removing sunken vessels by means of such large magnets acting on the plates. The large magnet here described acting on a plate 5 to 6 inches thick in contact with the magnet would have an attractive force of about 100,000 lbs. On a 3½" deck-plate, however, this lift would probably not exceed 10,000 lbs. See Figs. D and E—the effect of decreasing the thickness of the piece to be lifted is thus clearly illustrated. Thin plates cannot carry sufficient magnetic flux to render the magnets net efficient. The heavy plate can carry more of the total flux produced by the magnet, hence the combination acts more efficiently. The thin plate will not carry the large proportion of the flux is wasted by leakage thru the air, hence, the lesser lifting power.

With a 1-inch steel plate, covering about the same area as that of the magnet, the lift would only be somewhere between one and two thousand. The same results would apply to the 60- to 100-lb, steel billet, illustrated at Fig. F.

[Editor's Note:—As pointed out elsewhere in this issue, particularly in the article on "Magnetic Guns," it is possible to greatly increase the strength of electro-magnets momentarily by overloading them for a few moments. Prof. Birkeland, inventor of the most efficient magnetic gun design yet devised, thus manages to set up an almost indefinite field for a fraction of a second by greatly increasing the current past thru the magnetic coils. In most practical applications of the electro-magnet, however, the "ramping" of the magnet current is of little or no utility. A steady, even pull is most always desired and provided for.]

THE PHENOMENA OF ELECTRIC CONDUCTION IN GASES.

(Continued from page 94)

INCANDESCENT SOLIDS.

When metallic wires are heated to incandescent ions are produced. At low temperatures positive ions are usually given off and at higher temperatures negatives are also emitted. J. J. Thomson explains the production of ions by incandescence by saying that there must be free electrons in the metal which, when their kinetic energy is increased by the heating of the wire, finally break away from the wire as free negative ions. The production of the positive ions is more difficult to explain, as many experiments seem to show that they are not uniform in size, sometimes being much larger than the electrons. Evidently the heat and electrical energy together causes a disintegration in the wire itself which sets these particles free. C. T. Wilson devised a very clever experiment to show the existence of these particles about an incandescent filament. First he surrounds the filament with a gas and he then allows it to expand. At this point a visible cloud appears around the filament showing that in the neighborhood of the filament negative ions are set free and are given off by it, about which the moisture condenses to form the small visible drops of the cloud.

The salt of most any metal will produce ionization if thrown in a flame. Many phosphates, nitrates, and chlorides give off ions very readily. If thrown on the other hand, many other compounds give off negative ions freely, such as the oxides of barium, strontium, and barium. A carbonic acid contained in the filament is distinguished from most metallic filaments also gives off electrons when heated. It is this principle upon which the first arc was operated in which a current can be made to go from a separate electrode to an incandescent carbon filament, but not in the opposite direction. Something similar to this effect is also found in electric arcs.

ELECTRIC ARCS.

Dr. J. A. Fleming, who made a study of the Edison effect in carbon filaments, also made a special investigation of electric arcs, in which there are very great numbers of positive and negative ions. He found the positive pole to be worn out in a crater shape due to electrons emitted by the cathode striking it and dislodging large positive particles. He further found that if a set of terminals were connected to A and cathode C, Fig. 3, it was not necessary that both poles be incandescent and giving off ions. Fleming explored the arc with an auxiliary pole E, and he found that while the current-heating he could get a current between E and C but not between A and E, keeping E cold. In other words, he could get a current between two carbon ions when one was giving off negative ions, but not giving off positive ions. This he interpreted to show that comparatively few positives are given off and that the negatives carry most of the current. Such ions as these in electric arcs are very interesting on account of the number present and the fact that they are of many various types. It seems that the negatives are usually electrons, and the positives are frequently clusters or groups.

COLLISION.

Early scientists decided that if the pressure of a gas never decreases, the collisions of the molecules must be perfectly elastic, and this seems to be true at ordinary velocities. However, when two particles are moving fast enough collision will cause them to produce ionization, and the amount of energy which such a particle must possess represents what is called the ionizing energy. Furthermore, a modern scientist, Fertz, has proved that if a moving ion just

Measurement of Logarithmic Decrement

The condenser is set at the position of complete resonance as shown by the maximum deflection on the sensitive instrument, whose readings are proportional to $F$. The capacity is now decreased until the meter reads one-half of the former value, and the decrement formula, which can be independently rotated, is set at zero and clamped so as to rotate with the condenser. The condenser is now increased in capacity so that the meter reading at present 1/2 $F$ will increase to 1 and again decrease to 1/2 $F$. The scale reading may oppose the index mark $d$ is the value $6+\delta$, $\delta$ being the decrement of the circuit under test, and $b$ being the known decrement of the instrument.

By referring to the second article of this series, we see from the resonance curve that the ratio of change of capacity at the points corresponding to 1/2 $F$ are greater than at the point corresponding to 1 $F$, therefore, any decrement formula eliminating the necessity of locating the point corresponding to 1 $F$ is to be preferred, since the points corresponding to 1/2 $F$ are more sharply defined.

Important Notice to Subscribers

Due to the congestion existing at the present time in all railroad movements, also on account of the fact that many mail clerks have gone to war, there is a congestion of mails all over the United States. It may happen that your magazine will be slow in reaching you, and this delay may be from a few days up to several weeks.

Kindly bear this in mind before sending in a complaint, as the magazine will surely reach you in due time. Only after not having received a certain copy for a period of three weeks should a complaint be made.

You will confer a favor upon the publishers not to write until this time has elapsed, thereby saving them a vast amount of clerical labor.

The method of measuring the decrement just explained makes use of this very property and involves the formula:

$$\delta + \beta = \pi - \delta$$

which has been explained in a previous paper, $\beta$ corresponding to the capacity above resonance, giving current 1/2 $F$, and $\delta$, being capacity below resonance, corresponding to 1 $F$.

Fig. 4 shows a schematic diagram of the circuit of the Kolster decrementer. I is a single-turn coil which may be connected in the antenna circuit under test, and since the inductance of this coil is small as compared to the total inductance, the tuning adjustment will not be changed in the majority of cases.

The coil L is the inductor of the meter, either one of the three coils furnished with the various wave-length ranges from 300 to 2500 meters may be used. Coil $L$ is so arranged that the mutual inductance between it and coil I can be easily varied.

In order that the second coil may have reaction on the circuit under test, and also that the hot-wire instrument $H$ is not damaged by excessive current, the coupling between $I$ and $L$ must be very small.

$C$ is the variable condenser, independent of which the wave-length scale is attached, and to the scale the coil $L$ is geared to the condenser shaft in a 6 to 1 ratio, thereby opening the divisions on the scale in the ratio of 6 to 1. The scale has a zero point in the centre and goes to .3 on both sides.

A Matchless Book
At a Marvelous Price

IT COST $28,000 TO COMPILE THE CONTENTS OF THIS BOOK

THE ELECTRICAL EXPERIMENTER
VOLUME 5. 1917-1918

Our Bound Volume No. 5 contains a goldmine of electrical and scientific information. No such value has ever been offered before for so low a price. A marvelous cyclopedia of electricity. A reference book of authentic information not found in any other book in print.

Volume contains twelve numbers of the "Electrical Experimenter" magazine—May, 1917 to April, 1918, inclusive. There are 928 pages, 2,110 complete articles, 1,908 illustrations, 369 questions and answers.

Size, 12" high; 9" wide; 1½" thick.

A world of electrical information; the entire electrical Progress for one year; the greatest reference book on current "Wireless"—all at a price within reach of everybody. Mind you, the book is durably bound in attractive green linen with heavy covers. Letters stamped in gold. You will be proud to have it in your library. We have only 600 copies, therefore be sure and order to-day. Shipping weight 8 lbs. Add a sufficient amount for postage, otherwise we must ship by express.

NOTE: We also have a very limited quantity of Volume 4 (1916-1917). These books contain 992 pages, 1862 illustrations. The price is the same as for Volume 5. Positively the Greatest Electrical book bargain in the World. We ship AT ONCE. Order today to avoid delay.

Every Electrician Man Wants These Books and we ship them for your inspection FREE

Flexible Covers
Handy Pocket-Size Volumes

Just what you need to know to succeed in ELECTRICITY

EVERY electrician, every engineer, every mechanic should know about these wonderfully helpful instructive books, which give in plain words a complete working knowledge of electrical engineering in all its phases.

You run into some new electrical problem almost every day. The information you need to help you in your every day work is in Hawkins Electrical Guides.

Pocket-Size Flexible Covers

The books are small enough to slip into your coat pocket—handsomely bound in flexible black covers.

You can carry each volume with you until you have mastered its contents. 1,000 pages of verbal information and 4,700 illustrations. Once you see these books and put them into action use you will never again want to go without them. Try it at our expense.

READ THIS PARTIAL LIST OF CONTENTS

Electricity Only Taught.

This is not a school teaching many and various subjects. Electricity Only in all its branches is taught. Consequently, instruction here is more thorough; and you can learn more in a shorter time at less expense by enrolling with this school.

Courses Covered.

Courses here include Complete Practical Electrical Course, D. C. and A. C.—1 year; Commercial Engineering—2 to 2½ years; Electrical Engineering—3 years; also special 6 month courses in—Electric Trouble and Linemen; Electric Meterman; Electric Wireman; Electric Motor Repairman; Telephone Trouble and Repairman; Complete Draftsman Course.

Recognized Degree Given.

Bachelor of Science degree given to graduates in Electrical Engineering, under the laws of the State of Wisconsin, in 3 years. This further emphasizes this school's strength and standing.

Entrance Requirements.

Whatever your age, your past education or present ability there is the proper starting place for you here. The chief requirement is ambition to succeed. We will place you where you belong—in your chosen course—and advance you as rapidly as your work and willingness permit, consistent with thorough instruction and development.

School of Experience.

In addition to the practical training given here we have arrangements with a large number of Milwaukee concerns whereby our students can be employed part time and study at school part time, receiving salary for hours employed at regular salary scale. Thus many students obtain actual business and technical experience by direct contact with the business world while at school here, adding greatly to their development. Also, the salary earned pays toward providing students with additional funds while at school here and the outside activity interferes in no way with their studies, but increases their progress.

Ideal Student Environment.

Milwaukee is one of the world's leading electrical industrial cities. This is valuable study surroundings for the electrical engineer. Our city is one of the largest and most progressive cities in the country, having students correct social and living conditions. Milwaukee's situation and accommodation facilities make this city one of the best school cities in the United States. And the student body here is ideal companionship—industrious, ambitious, many young men of honest character. While the school's faculty and student system afford the same care and attention the student receives at his own school. All the environments for School of Engineering of Milwaukee students are for health, happiness, wholesome development and future sure success. The best school for you in every way.

Next Term Starts July 2nd

MAKE that day your starting day. Prepare now to enroll July 2nd. Join the great student body of industry, ambition and certain success here. Do not wait until later. Start July 2nd—or before; and be that far ahead in your great climb up the ladder of your sure Success. Clip the coupon at the left now mail it at once—and get full particulars of this great school and all the great advantages and success possibilities in store for you here.

Simplified Stenography

READ THESE AMAZING FACTS ABOUT K. I. SHORTHAND. This is a simplified system of shorthand easily learned in a few hours after which school and work may be written more quickly and accurately.

The old system

The old system, invented in 1827 by John Robert Gregg, has never been properly simplified. As a result, the shorthand student is often left without practice after leaving school and is not able to run shorthand—no need of a teacher.

The system of K. I. Shorthand is the system of King Institute at the exceptionally low cost of $1.00. Nothing further to pay and special instruction given without correspondence, if needed after you have obtained the course. Nothing such privilege given with any other low cost method.

Test for yourself, try K. I. Shorthand and you will find this system of shorthand is so easy to learn that school and work may be written more quickly and accurately. It is so easy to learn that it is a common remark for patrons to say they do not need to study—they absorb this wonderfully easy-to-learn K. I. Shorthand.

Why SO EASY TO LEARN

ELECTRICAL EXPERIMENTER
SIMPLIFIED Stenography

READ THESE AMAZING — absolutely logical — FACTS ABOUT K. I. SHORTHAND. This is a simplified system of stenography easily learned in a few hours, after which speed in writing comes with ordinary usage.

The old systems of shorthand are all right but are unnecessary for most of the practical purposes of life. By comparison you might solve a problem, using logarithms, that could be done more quickly and easily by simple arithmetic. In certain countries, a knowledge of engineering gained by intensive study for two or three terms is necessary to enable a person to operate a motor boat, yet here in America, even a girl or boy is able to run such a boat after a few hours of study and practice. Similarly with stenography—the simplified K. I. Shorthand enables a person, young or old, to sweep aside old-school restrictions and do practical stenography in an amazingly short time.

No need of a teacher to stand over you. K. I. Shorthand comes in books—complete—easy to learn in spare moments wherever you are. The system of K. I. Shorthand is the original and can be obtained solely from King Institute at the exceptionally low cost of FIVE DOLLARS. Nothing further to pay and special instruction given without charge, by correspondence, if needed after you have obtained the Course of Instruction. No such privilege given with any other low-cost method.

Test for yourself, the simplicity of K. I. Shorthand and the ease with which you learn by trying the short lesson below. The whole course is equally fascinating. It is a common remark for persons to say they do not need to study—they absorb this wonderfully superior easy-to-learn K. I. Shorthand.

You can set down words in K. I. Shorthand as fast as they are spoken or as rapidly as your mind logically acts when you are thinking out an essay, speech, directions, etc.

You can read your own notes—transcribe everything—word for word, accurately, weeks, months or years afterward. Your assistant can quickly learn to read and typewrite your notes.

One reason why K. I. Shorthand is so easily learned—and never forgotten—is that you are not (like the extensive, expensive systems) compelled to do light or heavy shading; or write in special positions above, on or below lines.

All superfluous technicalities eliminated; they are unnecessary for all ordinary purposes as is the kn o w l e d g e of trigonometry or ancient Greek language.

Try These K. I. Shortcuts

Association
This word takes 34 pen movements; in ordinary writing—only 2 in K. I. Shorthand. See how many times you can write it while your friend writes it the usual way.

Notwithstanding
Takes 54 movements in longhand; only 3 in K. I. Shorthand. The whole method is surprisingly easy to learn.

Representative
Takes 41 movements in longhand; only 2 in K. I. Shorthand. Learners, all ages, are delighted with their quickly attained speed.

TRY THIS LESSON
Here is a

All superfluous technicalities eliminated; they are unnecessary for all ordinary purposes as is the knowledge of trigonometry or ancient Greek language.

COMPLETE K. I. SHORTHAND

Complete $5.00

To

Readers of Electrical Experimenter
You know about electrical inventions that have simplified hitherto laborious mechanical processes. On the same theory—and proved by practice—K. I. SHORTHAND is manufacturing its remarkable time-saving merit both in the learning of it and in the facility with which the notes are transcribed. What other system of shorthand do you use? K. I. Shorthand with Study Card.

Even President Wilson has acquired speed and efficiency with K. I. Shorthand—advantage—we do many other men who do it for the first time.

Act upon your judgment NOW. Test our simplified or school BROCHURE EC-300, which demonstrates more fully your method is improved. It is the original and proven; the only system of simplified stenography perfected, with which the person who counts by mail is entitled to a refund of all money paid and all expenses.

SATISFACTION GUARANTEED

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.

TRY WRITE ACTING IN THE ORDINARY WAY...THE WAY SHOWN IN THE PLAIN AND SIMPLIFIED K. I. SHORTHAND.

See how easily you have learned to write a few signs in K. I. SHORTHAND. As you will learn the whole set at 30 per minute and attain speed you must write in a quarter to a half the time needed for writing in the ordinary way. Thus you may write as rapidly as the words are spoken.

HOW TO ORDER
Send $5.00 in full payment. Or, if more convenient—to save interest—$1.00 now and pay $4.00 when the Course of Instruction is received.

Bear in mind, we claim that the K. I. Shorthand is relatively worth fifty dollars and you are saving this amount. It is not only the most simplified, practical method for only five weeks study, but it is the only system of shorthand you can use in the most difficult of situations.

In the Lecture

Complete K. I. Shorthand System in accordance with your offer.

We present herewith two little instruments for which we have had a long and persistent demand. This outfit has been gotten up solely for the Experimenter and for this reason we are selling it "Knocked Down." In other words, the instruments come all ready for you to assemble, all the parts, screws, nuts, washers, etc., being furnished. Complete directions how to assemble accompany each set. With a pair of pliers and a screw-driver, the outfit can be readily put together in less than twenty minutes.

The most important point is that the telephone receiver spool comes already wound complete, and the Experimenter will, therefore, not need to wind his own spool.

The outfit when assembled comprises a highly sensitive CARBON GRAIN MICROPHONE with carbon diaphragm of exactly the same type as is used with our $15.00 Detectiphone. (See our Cat. No. 1.)

The receiver is a special low resistance double pole type with the difference that no magnet is used in the same for the reason that the function of this instrument is electro-magnetic, the same as all loud-talking phones.

The spool is wound with special enamel wire for five ohms, standard with our Detectiphone.

This instrument works best on four dry cells, and particular attention is called to the fact that in order to work, the loud-talker requires a fairly heavy current and for that reason thick wires must be used for connecting the transmitter with the loud-talker. If this is not done, the voice will be weakened considerably. If no heavy wire is at hand, more batteries must be used to compensate.

USES: This instrument can be used to transmit phonograph music from one room to another; used as a Detectophone; as a Radio Amplifier; as a telephone extension by placing the regular telephone receiver against the sensitive transmitter with the loud-talker; for salesmen to talk through window (Loud-Talker outside in street, microphone transmitter for salesmen, talking into same); for restaurants for talking to the chef, and a hundred other uses. Many young experimenters are developing a lucrative business selling this appliance to various merchants at a good profit.

Outside of the two instrument parts, one three-foot cord is furnished with sensitive microphone as shown; instructions, etc., are furnished.

No. AEK204 "Electro" Loud-Talker Outfit Parts "Knocked Down," complete...

No. CEK205 "Electro" Loud-Talker Outfit, same as above except that it is already assembled and tested at factory...

S. O. S.!! A REAL ELECTRIC

Learner's Telegraph Outfit for 25c Prepaid

In the 15 years of its existence our company has never offered such a bargain as the present one. Just think of it, a real electric learner's telegraph outfit with which to learn the code or to telegraph to your friend six blocks away, for 25 cts.!! Impossible—you say. Quite so. We do sell them at cost, but we do it solely to get you acquainted with us and place our wonderful catalog in your hands. And if this telegraph pleases you, you will order other things from us. This telegraph has a red-lacquered wooden base, strong electromagnet, nickel binding posts, generous telegraph knob and nickel clicker. Telegraph measures 3 ½ x 1 ½ x 1 ½ over all. Full directions for learning the code and for the CODE CHART are given with the telegraph, all packed in neat box. Telegraph works easily on a single dry cell. Two instruments may be ordered for 50 cts. if wanted, to telegraph between two rooms or two houses.

If the telegraph does not come up to expectation will cheerfully refund money. Boys order 6 to 25 of these instruments. Sell like hot cakes to friends for 30 to 40 cts. each. So small can be slipped into pocket. LEARN THE CODE DURING SPARE TIME. TELEGRAPH OPERATORS ARE SCARCE.

UNCLE SAM NEEDS THOUSANDS.

Important. As this telegraph is sold at cost, we reserve the right to decline your order (by refunding the money) unless you order one of our Free Cyclopedias at the same time. Should you already have our Cat. No. 19, it is necessary to cut out the coupon, writing across it: I have Cat. No. 19.

This is done for the guidance of our checking department. Of course, if you have Cat. No. 19, you need NOT send for it again.

We are prepared to fill orders for 10,000 of these telegraphs this month. They are in stock NOW. Your order will be filled within 72 hours.

"THE LIVEST CATALOG IN AMERICA" Our big, new Electrical Cycloedia No. 19 is waiting for you. Postively the most complete Wireless and electrical catalog in print today. 200 Full Pages. 500 illustrations, 500 instruments and apparatus etc. Big "Feats on Wireless Telegraphy," 20 FREE coupons for our free Cycloedia No. 20: "Inventors" Free Cycloedia No. 19 measures 7 ¾ x. Weight 2 lb. Beautiful stiff covers.

"THE LIVEST CATALOG IN AMERICA"

Now before you turn this page write your name and address on coupon at right, cut out, number 6 cts. stamps to cover mail charges, and the Cycloedia is yours by return mail.

THE ELECTRO IMPORTING CO., 231 Fulton Street, New York City "Everything for the Experimenter"
SCIENCE AND WAR

E read a good deal lately about the futility of science in general, and the cry is long and loud that much vaunted science instead of civilizing and preventing wars, actually brings about wars and prolongs them. Parlor critics and the lay press, particularly, when things go right, are wont to ask cynically what science ever did to prevent wars, or if that were impossible, what it accomplished towards shortening wars. Science is credited with accomplishing nothing but murderous machines and devices and of calling into being destructive forces without end. Science, in short, is held up to us as a modern Frankenstein Monster, which, escaping from our laboratories, now runs rampant and wreaks vengeance not alone upon those that brought it into being, but upon our entire civilization as well.

As to science creating wars, we might state that there have been wars ever since animal life appeared upon this planet. War is a natural phenomenon, the same as, let us say, a volcanic eruption. Neither is it confined to man alone. It is the eternal war for supremacy, whether it be the fight to death between two roosters, or the war between two great animal nations, such as for example, the witnessed in ants, where hundreds of thousands are fighting for an equally large horde of supremacy, killing and maiming thousands and bringing back vast numbers as prisoners, henceforth to become slaves.

If we would only accustom our minds to the great and outstanding fact that there will be wars, small and large, as long as the earth endures, we would think of war in a totally different manner.

Therefore if we cannot altogether prevent war, with the aid of science we can certainly very largely prevent its former horrors and perhaps shorten it. Any student of history knows that creeds have become less and less frequent as the centuries roll on, while statistics go to show that, considered as a whole, there have been far fewer wars during the past century, which marks the real beginning of science. As to the murderous war inventions created by science, such inventions only seem so murderous to the uninformed. Statistics show that far from killing more people, the reverse is the case. The number of men actually killed in action, as hit by cannon, rifle, poison gas and what not, is less than 5% of the total casualties. Even now, more men die from natural causes or from bodily diseases than from man-made scientific frightfulness. There were more people killed in the United States last year by automobile and railroad accidents, casualties in factories, etc., than were killed on the road by war. A careful study of statistics will bear out this statement.

In the former great wars as high as 70% of the effective fighting forces were lost by the ravages of disease, such as cholera, typhus, etc. Napoleon’s great army after the return from Russia had dwindled down to less than 25% of its former strength, mainly thru disease. These were the former great horrors of war, now entirely conquered by science. Modern surgery, anesthetics and medical science as a whole are daily reducing the death toll among the unfortunate fighters struck down by the hand of man. Where formerly over 90% of the casualties of war thru disease was eliminated, this percentage has been reduced to less than 20. In other words out of one hundred maimed soldiers less than twenty now die of their wounds. While the entire balance may not be again fit for actual fighting, this vast percentage of disabled humanity is returned more or less intact to its peaceful pursuits. While it is not our intention to call war a benefit to humanity, the fact can not be denied that it has given medical science a wonderful opportunity to make new and important discoveries, to greatly reduce suffering, as well as treating diseases more intelligently hereafter.

Medical science alone has vast opportunities during the war, because it has more human material to work upon than in peace times. The fallen soldiers will therefore not have died in vain. Each one of them will prevent thousands of others from dying during the peace that is to come.

H. Gernsback
'LEARN BY DOING'

The Only Way to Learn Electricity

The only way you can become an expert is by doing the very work under competent instructors, which you will be called upon to do later on. In other words, learn by doing. That is the method of the New York Electrical School.

Five minutes of actual practice properly directed is worth more to a man than years and years of book study. Indeed, Actual Practice is the only training of value, and graduates of New York Electrical School have proved themselves to be the only men that are fully qualified to satisfy EVERY demand of the Electrical Profession.

At this "Learn by Doing" School a man acquires the art of Electrical Drafting; the best business method and experience in Electrical Contracting, together with the skill to install, operate and maintain all systems for producing, transmitting and using electricity. A school for Old and Young. Individual instruction.

No previous knowledge of electricity, mechanics or mathematics is necessary to take this electrical course. You can begin the course now and by steady application prepare yourself in a short time. You will be taught by practical electrical experts with actual apparatus, under actual conditions. 5,000 of our students are today successful electricians. Come in and read their enthusiastic letters. Let us explain this course to you in person. If you can't call, send now for 64-page book—it's FREE to you.

SCHOOL OPEN ALL SUMMER.

UNUSUAL FACILITIES FOR PROVIDING ROOM AND BOARD AT LOW RATES

NEW YORK ELECTRICAL SCHOOL
29 W. 17th St., New York, N. Y.

Liberty Bell Heard O’er the World Via Radio

By THOMAS REED

E ver notice how Tyranny always runs true to form? Take the average baby. Having reduced his home to subjection — buffalosed, bullied and seduced it to a finish—he picks the moon as the next subject for “annexation and indemnity”: which process the moon resists, in its unwarmed, moonlike way. Action and reaction being equal, the moon probably suffers somehow for its temerity; but the principal effect is observed on the foiled baby, in the well-known everyday domestic phenomenon of “tantrums.”

When this happens, good nursery-psychology recommends diversion of the infant conqueror’s mind by dangling before him any handy object, exclaiming, as engagingly as possible, “See the pretty doggy!”

Copyright by E. P. Co.
or whatever Common Parliament names the selection. You find the same psychology applied to the spasms of the undeveloped "nondescript" wisdom behind the disarrangement in his Paris time-table, and the unaccountable hitch in his Pictorial "negotiations."

The "doggy" in his case—the Nauen wireless-station—inspires this remarkable declaration:--

"From the formidable towers of this establishment, we have the gigantic rays of which surpass all the fables of antiquity, waves are incessantly sent forth which acquaint the listening nations with everything that is in our judgment they ought to know. This wondrous invisible committee, moreover, has consistently kept us apprised of events which the enemy would gladly have withheld from us."

Gosh! The Fables of Antiquity certainly have been outstripped; and the screen shown an innocent Nation cocking its ear to catch, amid a world of deception, the only clear, snappy, reliable TRUTH, "made in Germany" expressly for its enlightenment; and in the excitation being pitted of a shy heart-throb—such as a Declaration of War! They say they are always efficient, and this patent "divertor" of theirs proves it. It's a fine divertor. It would divert anybody.

But while the bistoring is good! I have an idea.

You remember, a few years ago, how Mr. Carty, the Telephone Wizard, with his "Audittle" and various do-fummes, talked by wireless around half the world? Well, what's the matter with ringing 'em up again, and sending out a boom from the

"Chaukendew Zeitung, quoted in Boston Transcript."

---

Hats off to Thomas Reed! Here is the germ of a wonderful idea—and a typical American idea, too. Not so long ago Mr. Carty of the American Telegraph and Telephone Company succeeded in making the human voice heard by Radio half way around the earth. The voice of the operator, stationed at Washington, was heard in Paris, France, and as far as Honolulu.

Mr. Reed suggests to transmit the metallic voice of old Liberty Bell by Radio thru the ether over this war-wrecked earth of ours, symbolizing the voice of Liberty in the most unique fashion possible. Yes, the German station at Nauen would hear the voice of Liberty Bell, too—Liberty ringing its way thru the ether, in advance of the American Army. The plan is simple and practically costless, as all the apparatus are on hand. What better date could be selected for the momentous event than July 4th, 1918. Let us hope that it will come off.

Readers, Wireless enthusiasts! When you see this in print write or telegraph to the Secretary of the Navy, the Hon. Josephus Daniels, Washington, D. C., asking him to send the voice of old Liberty Bell ringing over the battle-fields in France, on to Berlin, on July 4th. If 100,000 of you urge Washington, the great event will come off—a monument of the solidarity and enterprise of American Amateurs. Show this article to your local paper and urge it to reprint it at once, sending a clipping to us.

Now all together Amateurs! Show the nations that you are still on the map!

---

Liberty Bell, in Independence Hall?

And for a starter, what's the matter with mending our Bell, so we can boom it, good and proper? It's curious that while the "whole push" from song-writers up (or down) to financiers, are calling for the Liberty Bell to "ring again," they seem to mean the ring was formerly cyclical, but it's cracked. But say, what does a crack amount to in any metal object, in these days of arc and acetylene welding? Science has moved on since we set the Bell away on a velvet cushion, and entered it up as "incurable." Broken cylinders and flywheels are being welded every day—huge things, beside which the Liberty Bell would look like a toy; mended, not merely to ring, but to resist high steam-pressure and enormous centrifugal force, and actually strong for every ward than before, since the original flaw has been eliminated.

Sure, it's the simplest thing in the world to fix our Bell, unless we prefer it broken and out of commission. But why should we—our Liberty isn't in that plight! Up to a certain point, the Bell for America was pretty closely. We founded our Freedom in 1776, and the Bell rang for us. But then the casting of our Independence, which we couldn't do before, and that's all. The casting of the Liberty Bell, which worked and widened till it broke the Nation apart; while the Bell, too, developed and expanded, and cracked from it. We welded the Nation's fracture together, better than any other castings. But there, the Bell stopt accompanying history, and the reason's why it wouldn't catch up again, now that we're setting our Liberty to the biggest job of her life.

I sure wish that old Bell was fast, and Mr. Carty's rinktums were working to and fro. If it were possible to arrive at a certain appropriate moment, when all radio traffic should stop, and for one whole minute the ether, everywhere around the world, should hum with "Liberty Vibrations" alone.

Anyhow, for the "Hum," up there in the "formidable towers," that would be a reminder of what Pioneer Peoples do to the Posts of the earth. He's had examples, in "Pats" and "Anzacs"—I name'em with respect. What with Indians and bears, rattlesnakes, bad-men, gypsy-moths and Trusts (to mention only a few of our Nearest and Dearest) we're so accustomed to swatting "vampires" that eyes can't see them. But if radio power or two come all in the day's work. With an "Ah there, neighbor!" for the new arrival, we should be over the kinks, and, whistling and busy, get after him.

Well, perhaps my scheme is only a pipe-dream. But 'you know me, Al!—while my hopes are small of entertaining an angel unaswares, I never 'ould turn away a needy pipe-dream from the door!

---

A CENTURY OF LIGHT.

1815 to 1855, sperm oil and candles, average home used 25 candle hours in light, or 9,000 per annum—cost $22.

1855 to 1865, kerosene introduced with 50% more light, same cost of $22.

1865 to 1875, kerosene and gas—average household used 20,000 to 30,000 candle hours—cost $23 to $34.

1875 to 1885, kerosene reduced to 2½ a gallon, gas to $2 per 1,000 cu. ft.; average family used 76,000 c. p. hours per year—cost $30.

1885 to 1905, kerosene disappearing—primarily due to gas mantle coming in, 200,000 c. p. hours average family used per year—cost $30.

1905 to 1915, average gas c. p. hours, 200,000. Average electric c. p. hours, 123,000 (due to saving thru switches)—cost $15.

Maximum increase of average families, 360 candles, or about 18 times that of a century ago.

With increase of 1700 per cent in amount of night lighting, reduction in cost to lighting is about 70%. Express another way, the cost of lighting per unit candle hour is less than 3% of what it was in the first half of the period.
Science and Radio in New Film Dramas

THERE seems to be no dearth of the "scientific movie" from present indications, with the vast number of serials and individual photoplays that are appearing all over the country. With the public mind literally fed up on the work of the German spies thru the daily papers, it is only natural to suppose that the screen should reap a rich harvest with film dramas showing these inner and secret workings of the Imperial German Government's espionage system in a graphic form.

First and prominent amongst these is the "Eagle's Eye," showing the story to which the German Government has resorted to hamper the work going on in this country. It is shown how a German agent's laboratory was raided by the U. S. Secret Service and the compositions discovered there tested, with the result that numerous bottles were found to contain disease germs of various kinds to be used in causing an epidemic of sickness among the longshoremen of New York, in order to paralyze the shipping of supplies to the Allies.

The upper left photograph shows the wireless room of the Criminology Club of New York City. This club is a composite organization representing the Secret Service used throughout "The Eagle's Eye" to picture the activities of the body headed by Chief Flynn, the author of the picture. The picture shows a call being received, summoning the members to the Jersey stock yards at the end of the line to burn several thousand bales of cotton and horses by the Imperial German Government, was discovered.

The remarkable "Life Restorer" pictured here (center) plays an important part in one of the closing episodes of Pathe's new serial "The Hidden Hand." After many thrilling and exciting incidents in which an heiress and a Secret Service man, who is trying to prove the girl's identity and finally "falls" in love with her, figure prominently, we arrive at the scene where the villain of the thriller known as "The Hidden Hand" has been mortally wounded and his followers carry him away unconscious. They try to revive him, but without success and then "Verda," his right hand man, orders the henchmen to try the electric re-suscitating apparatus on him. By its means he is brought back to life. The machine is essentially a large static machine and is very realistic in the semi - darkness with its large spark discharges in full operation. The basis for the introduction of the machine has been conceived by the author, Arthur B. Reeve, writer of the Craig Kennedy stories.

Last but not least we come to the General Film Company's new patriotic spy movie. "I'm a Man," in which Radio telegraphy plays a prominent part. (Lower photo.)

Frank Eisel, the son of German-born American parents, is a member of the High School Cadets. Frank's father is a banker who is desirous of having his daughter, Ruth, marry a Frenchman named Decourcy, a director of the bank and very wealthy. Ruth has another admirer. David Smith, a young bookkeeper in the bank, but their growing attachment is frowned on by the father who favors Decourcy. One day Frank notices a poster reading "Beware of Spies" and turning, sees Decourcy talking with a stranger, and he at once suspects the Frenchman of being a spy. Events prove that he is right, as Decourcy reveals himself to Frank's father as a German spy who has been masquerading for ten years as a Frenchman. On account of operations made thru the bank, he not only compels the banker to keep silent, but insists that he be received into the Eisel home.

Here he learns of Frank's amateur wireless outfit and demands that the father get the boy out of the way so that he may use it. This the father does, but Frank returns unexpectedly and intercepts a message regarding the burning of some oil wells, and he saves the wells at the risk of his life. When Frank is hovering between life and death, Dave Smith, now the accepted suitor of Ruth, notices a change in the boy's condition and instantly springs to the boy's side, revealing a secret service badge that he is wearing. Thus Frank knows that his father is no longer under suspicion, and the banker is also overwhelmed with joy, realizing that Smith knows he is a true American, and he turns to Frank saying, "Frank, my son, you are a man!"

The photograph shows young Frank Eisel operating his radio set while in close proximity may be seen his young lady love, Miss Dolly Hope.

The chief inventions used in the present war as distinguished from the Napoleonic wars: Steamship, submarine, air craft, high-power guns, smokeless powder, breech-loading gun, rapid-fire gun, revolver, automatic pistol, telephone, wireless telegraphy, automobile, poisonous gas.
Electric or Steam Railroads—Which?

By H. WINFIELD SECOR, Assoc. A. I. E. E.

YOU stand enthralled in a beautiful gorge among the Rockies, admiring the supreme grandeur of nature, when—with a roar like distant thunder—a long, snake-like train of steel cars, headed by a smokeless demon that fairly bristles with power, dashes by you at a mile-a-minute speed.

more or less interested in the comparative costs of operation for such electrification, and always, always the question comes up—Will it pay? The answer has been pretty well settled by the facts and figures presented in the past year or two by our ablest engineers, and particularly by the report of the railroad operating the long-

Notable among large steam railroad electrifications are the following: 1896, Baltimore & Ohio Tunnel; 1906, New York Central Terminal; 1906, West Jersey & Seashore; 1909, Great Northern; 1910, Detroit River Tunnel; 1910, Pennsylvania Terminal at New York; 1911, Southern Pacific; 1913, Butte, Anaconda & Pacific;

It’s the Chicago, Milwaukee and St. Paul R. R. “Olympian,” the finest transcontinental train in the west, speeding on her way to the Pacific coast. She’s driven by “juice”—3,000 volts of it, and thousands of amperes, all transmitted over a thin copper wire from mighty water-falls, high up in the mountains. There the electrical engineers have placed their electric generating stations, where gigantic turbines spin the dynamos all day long, reclaiming the power in the water—at present over 150,000 horse-power is developed by these hydro-electric plants, the most efficient of all methods in the production of electrical energy.

Now that the whole country has been aroused as to the countless possibilities of electrifying the railroads, and other arteries of commerce and industry, by the recent reports from engineers connected with the national government, everyone is est electrified mileage in the world, the Chicago, Milwaukee and St. Paul system, which now haul all their passenger and freight traffic over the Rockies from Har- lowton, Montana, to Avery, Idaho, a continuous run of 440 miles. This railroad is now arranging to “electrify” to the Pacific coast, so successful has the present installation proved. This is what Mr. C. A. Goodnow, assistant to the President of the C. M. & St. Paul R. R., in charge of the electrification, recently said: “Our electrification has been tested by the worst winter in the memory of modern railroad engineers. There were times when every steam locomotive in the Rocky Mountain district was frozen, but the electric locomotive went right along. Electrification has in every way exceeded our expectations, not only as respects tonnage handled and mileage made, but also the regularity of operation.”

1916, Chicago, Milwaukee & St. Paul; 1917, Victorian Railways, Australia; besides a host of others now joining the ranks of believers in railroad electrification.

We may profitably study for the moment this wonderful engineering feat so successfully carried out on one of the greatest railroads in the West.

The tracks of the mountain district of the Chicago, Milwaukee & St. Paul Rail- way, in surmounting the obstacles imposed by the Rocky Mountain and coastwise ranges, represent the solution of one of the most difficult problems ever mastered by railway engineers. Out of this section of rugged mountain railway, including many long grades and short radius curves, four steam engine divisions were selected for electrification, aggregating 440 miles in length. Steam engines were first abandoned on the Three Forks-Deer Lodge division,
115 miles long, and crossing the main Continental Divide, thus giving the electrical equipment its initial tryout under the severest service conditions of the entire system. The first electric locomotives were placed in regular service on December 9, 1915, and during the month of April, 1916, service was extended to Harlowton, making a total of 220 miles of electrically operated road. By the first of November, 1916, steam engines were superseded over the entire distance of 440 miles, from Harlowton, Montana, to Avery, Idaho.

This project is the most extensive steam railway electrification in the world, the length of haul being nearly six times as great as any trunk line now operating with electric locomotives. The length of track between Harlowton, Montana, and Avery, Idaho, is approximately equal to that from New York to Buffalo or from Boston to Washington.

In crossing the three mountain ranges included in the electric zone, there are several grades of one per cent or more, the most difficult of which is the 21-mile, two per cent grade between Piedmont and Donald, and the longest the 49-mile one per cent grade on the west slope of the Belt Mountains.

The curvature is necessarily heavy, the maximum being 10 degrees. There are also numerous tunnels in the electric zone, 36 in all, of which the longest is the St. Paul Pass tunnel, over a mile and a half in length, thru the ridge of the Bitter Root Mountains.

The passenger service consists of two all steel finely equipped transcontinental trains in each direction, the "Olympian" and "Columbian," and a local passenger train in each direction daily between Deer Lodge and Harlowton.

Freight traffic thru the electric zone comprises from four to six trains daily in each direction. Westbound, the tonnage is made up of manufactured products and merchandise for Pacific Coast points and foreign shipment. Eastbound tonnage includes grain, lumber, products of the mines and some live stock.

Electrification promises a very marked reduction in running time, not to mention the freedom from cinders and smoke always incident to the use of steam locomotives. It has been found, for example, that on the 21-mile two per cent grade from Piedmont to Donald, the electric locomotive can reduce the running time of passenger trains from 65 minutes to approximately 41 minutes. On the run from Deer Lodge to Butte, which, under the steam locomotive schedule, required an hour and 20 minutes (80 minutes), a saving of approximately 30 minutes can be made.

In the freight service, it has been found that on the first division where the steam locomotives have required 10 to 12 hours to make 115 miles, electric locomotives can meet a schedule of from seven to eight hours for the same distance. The heavy grades and frequent curves at certain points offer serious obstacles to steam locomotive operation even in the summer time, but with winter temperatures as low as 40° F. and heavy snowfalls in the Bitter Root Mountains, serious delays have occurred, owing to engine failures or to inability to make steam. The capabilities of the electric locomotives are in no way impaired by cold weather or by inability to obtain fuel or water in case of snow blockades. During a series of record-breaking temperatures in December, 1915, the powerful Mallet engines were frozen up at different points on the system and the new electric equipment was rapidly put into service to replace them. On several occasions electric locomotives hauled in disabled steam engines and trains which would otherwise have tied up the line.

In cold weather, such as we experience right thru the winter in the East, not to mention 40° to 60° F. in the West, the steam locomotives suffer severely in loss of all-around efficiency. The severe cold makes it harder to keep the boiler parts heated up, and even the best from the coal is used up simply to raise the water to the steaming point, owing to its extremely low temperature. The steam locomotive is about the most inefficient prime mover we know of for practical purposes. It practically never realizes above 7 to 8% over-all efficiency—i.e., in transforming the energy of the coal to tractive force at the driving wheels and draw-bar. The remaining 92 to 93% is wasted in friction and heat losses.

Recent tests in the locomotive laboratory of one of the largest American railroads have shown that under road conditions the best steam engine realizes nearly 7% than 

(Continued on page 207)
How Uncle Sam Tests Coal by Electricity

By SAMUEL COHEN

HOW much heat do we get from different grades of coal? This is the very real and important problem that confronts our manufacturers in operating their plants. The subject of determining the heat unit value of coal and its ash matter is a very important factor to be considered. Briefly, the analysis of coal is as follows:

First, in burning coal, five main points must be considered:
1. The amount of moisture, volatile combustible matter, percentage of ash, sulfur, and calorific value. The latter is the one in which we are mostly interested in the present instance, since electricity plays a very important role in its determination, while the first four items are determined by purely chemical methods.

The coal sample in question goes thru a regular analysis before it is cast and the results of the approximate analysis gives only a general idea of the heating value, by indicating the class in which the fuel belongs. Glimpse of anthracite coals can be characterized by a small percentage of volatile combustible matter (usually less than 10 per cent), while bituminous coal contains a large amount of this constituent (usually 30 to 40 per cent), while in cannel coal this is the main constituent. The proportion of this constituent is dependent on the amount of hydrogen present, as this element forms volatile compounds with the carbon. When hydrogen burns, it evokes a much larger amount of heat than is produced by the combustion of the same amount of carbon. Coals containing a large proportion of volatile combustible matter have usually, therefore, high calorific values, and water which absorbs heat when it is converted into steam. It is evident that the calorific value of a fuel can be calculated from the percentage of carbon and hydrogen present. This method is subject to an error, arising from the fact that the heat combustion of hydrogen and carbon varies with the nature of their chemical combination. Direct methods for determining calorific values are therefore more reliable. The instrument devised for this purpose is called a calorimeter. The calorimeter consists of three essential parts, namely:

1. A combustion chamber, a tank of water with a delicate thermometer for indicating the amount of heat absorbed, and an insulating device to prevent the external heat from reaching the water and the thermometer, and also to prevent the heat generated in the combustion chamber from escaping the apparatus.

A certain quantity of the sample coal is placed in a small container. This quantity is usually one gram. With this coal a certain amount of oxidizing agent is added, and this may be sodium peroxide. In the same container a fuse wire is placed and properly connected to an electric power source so as to ignite the coal mixture at a desired time. The upper right hand photograph shows clearly the sample of coal in the calorimeter capsule. Note the fuse wire on top.

The temperature of the coal when in a burning state is directly determined by means of a special electric thermometer which is inserted in the coal chamber. This thermometer consists of a fine high-resistance wire, whose resistance is determined at the beginning of the test and at the period of combustion. The resistance increases with temperature rise, and since there is a definite relation between temperature and resistance, it is therefore possible to determine the temperature corresponding to the resistance. So by measuring the resistance of the wire in the coal chamber at the period of combustion, we derive from it a mathematical relation of the temperature, and from that the calorific value. The photograph at the upper left hand corner shows a special accurate slide-wire bridge for measuring the resistance. The bridge wire is supported on the drum of the apparatus. The lower photograph shows four of these calorimeters. The wires are used to connect the igniting fuse wire with the current supply, while some of them run to the electric thermometers.

This work is of extreme importance insofar as it tells the purchaser the maximum amount of heat he can possibly obtain from a certain grade of coal.

ELECTRIC SAW MILLS.

Electrically operated saw mills of the portable type are said to be rapidly gaining in favor among lumber men. In localities where water power is abundant and has already been partially converted into cheap electric power the portable sawmill is especially popular. According to the president of a firm which is manufacturing electric portable sawmills, the demand is fast increasing in the South and West of the United States at the present time.

TELEPHONE CABLES IMPROVE WITH AGE.

It is found that the insulation resistance of telephone cables increases with the age of the cable, when it lays in the ground, because the moisture it possesses appears to be dried out.
NEW DENTAL AND X-RAY MOVIES.

D. R. E. L. CRUSIUS of New York city has announced that in co-operation with one of the leading film companies he has perfected a system for taking X-ray moving pictures which is expected to be of great service in treating injuries to the joints.

Among the pictures taken thus far are illustrations of the movements of the knee, ankle, and elbow. Dr. Crusius says that the photographs show not only the bones but the muscles, and that by moving a joint that has been injured and photographing the action of muscles and movements of bones it will be possible to find out just what parts have been injured and the treatment required.

A physician desiring to have the heart of his patient tested sends him to a radiologist to have an X-ray taken. The picture can show the size, position, and appearance of the organ, but it can not show the rising and falling of the heart beat. Again, the radiologist, during the examination, can take note of the manner of the beat, but he cannot pass his observation on its actual form. The same is true of X-rays of the lungs, stomach, intestines and other organs; than can not be shown functionally. An X-ray photo of the living stomach is shown herewith. Thru the use of the new machine radiological people. Most every one has read of the wonderful work done by the Italian army this past winter in the mountains in the campaign against the Austrian army; of the almost insurmountable difficulties that have been met and overcome, and it is only thru the medium of the moving picture that one is able to grasp the significance of this vast work.

We see the Italians transporting guns over the mountains by means of long steel cables and aerial cars or bombarding the enemy during the night under the glare of a hundred powerful electric searchlights. In the morning following, the infantry takes up the charge to gain and consolidate the ground which has been cleared by the heavy shell fire, and it is during these scenes that the dangers the camera man is exposed to, with the hail of bullets ringing the machine wherein he looks like the proverbial peanut on the watermelon.

The full significance of photography in the World War can only be realized in a small way from this brief resume of course, and only when we have returned to peaceful pursuits again and witness all that has been preserved thru the medium of the photographic film and plate will we fully appreciate the invaluable records that we can pass on to posterity.

The American Army now in France is being equipped with all the latest electrical appliances. Searchlights mounted on telescoping towers are being supplied to our forces as fast as conditions at home will permit. The other presents a complete root filling and the amputation of the same tooth. Many teeth now sacrificed may be successfully treated and give life-long service.
Will The Germans Bombard New York?

By H. Gernsback

Of late we have been reading quite a good deal in the daily press about the possibility of an aerial attack on American cities by the Germans. Many anxious inquiries have come to the writer's desk from readers of this periodical, asking if there was any chance or probability of an aerial raid at this time. Many people seem to think that raids are impending this year, while equally as many are skeptical about it. It is the purpose of this article to point out certain relevant facts relating to the above, and we will try here to show the technical aspect of the idea.

It does not bring a military advantage. What the lay critics seem to leave out from their reflections entirely is this: If the English or the French were positive that the Germans would not or could not bombard their cities, they would not have to keep hundreds or thousands of aeroplanes inland for defensive purposes, and these aeroplanes could then be used to the greatest advantage at the front.

In other words, by sending, say a dozen, bombing machines over London, Germany effectively ties up several hundred English aeroplanes inland, which then obviously cannot be used against the Germans either at the front or to bomb German cities. Therefore, it is good business from the German viewpoint to send a few machines over London or Paris at irregular intervals, thus locking up a large quantity of English or French aeroplanes that might be used to vastly better advantage against the Huns. This is the main reason, and probably the only reason why these raids occur and from a military viewpoint must occur. The Germans have no choice about it, for if they did not do it, the Allied aeroplanes would overwhelm them at the front.
preme effort to slip thousands of aero-
planes to Europe. The ocean lies between
us, and we are in a way comparatively safe
from aerial attack.

The German military command, however,
cannot view the situation but with great
alarm, and in self-protection it will be nec-
essary to establish a vast network of Ameri-
an aeroplanes on our own shores, if the trick can be done. In other words, the Germans will try to cut us off from shipping all of our aeroplanes to Europe, and they will stop at nothing to gain their end. Blowing up factories and military camps in America by their agents
will not help them much, and they will not
be able to torpedo but a very small percent-
age of our total tonnage of these aircraft.

What simpler remedy then is there for their
problem than to bombard occasionally, say,
New York, Boston or Philadelphia, thereby
practically cutting us off by a vast fleet of
aeroplanes. This is the military
aspect of it and for this reason it would be
safe in allowing ourselves to live in a fool's paradise. We should always
remember that we are facing a formidable
enemy who stops at nothing to gain his end, and the German army and navy do
to often accomplish the impossible. 

Witness the 76-mile gun which was so prepos-
teriorly described in "Flying With"—an armoured battle-plane,—
which has just made its appearance over the
Allied lines to our great discomfort. The
plane is so large that even a skilful pilot
does not dare to be an alarmist, there is but little doubt
that some of our American coast cities are in
for an aerial raid. But how can it be
accomplished?

Zeppelins may safely be left out of con-
sideration. These huge aerial sausages
have already been surpassed by the British
as well as the French, and they do not venture
to face us on the flight of their lines.
They are too vulnerable, offer too big a
target, and are easily shot down by anti-
aircraft guns, as well as by attacking aero-
planes. There seems then little possibility
of a Zeppelin making its way over the
Atlantic at the present time of writing. Even
in peace times it is questionable if a Zepp-
elin could cross the ocean at the present
day. The tremendous weight of the
fuel alone is against such an undertaking.
Aeronauts, let alone carrying bombs,
average atmospheric conditions, etc. This
leads us to the question of a Zeppelin.

While it seems quite possible, and as a
matter of fact very probable, that the At-
lantic will be crossed by an aerial vehicle
shortly, we have no assurance that the
Germans have built super-submarines from
to ten thousand tons, and we under-
stand that some have actually been 
launched. We know that submarines can
readily cross the ocean, as has been proven
by the Deutschland as well as by our own
submarines, but we have no assurance of such a craft not only the Atlantic Ocean, but the Pacific
as well. If the Germans have a 10,000-ton
submarine, it will be a very simple matter
to have a craft of such size immersible anywhere from three to five
"knocked-down" aeroplanes, and which can be
readily flown off in a few minutes' time on a temporary platform on top of
the submarine.

This problem offers no technical difficul-
ties. If aeroplanes can be launched from
a submarine, it has been declared as eminently feasible by
many authorities. A submarine as large as
ten thousand tons has quite a breadth, and is of course of great length. A light steel
or wood platform can readily be put in
place within a few hours' time, and then
the crew will find but little difficulty in assem-
bling and launching it from this platform. Our front cover shows the idea
better than words, and we are leaving the
details to the reader's imagination. We
again wonder to what extent it will be
a comparatively simple matter for
the Germans to do this. If the attempt is
made the Japs will probably send over a
number of submarines, several of them being
used to carry aeroplanes only, the others
to act as a sort of guard to ward of hostile
vessels. And the attack will most likely
be made at sunset when the air is usually
calm, and when the submarines will stand
thereby...

THE AUGUST "E. E."

Among one hundred other timely
articles to appear in the August issue are
the following, which cover the fields
of Electricity, Radio, Physics, Experimental
Chemistry and Astronomy.

An "Aerial Mono-Rail Flyer of the
Future"—It flies along on a single
steel cable at 200 miles an hour, A
dream of to-morrow, based on facts of
to-day.

Recent Developments in New
tyork's subway system.
A Page of Electrical Summer-time
Comforts.

Diamonds and Rubies Made to
Order—-rate of the Electric Furnace
Coupled to Modern Industry, by George Holmes.
The Spectroscope and How to
Build One—written by an expert
beginners in the art of spectroscopy.
A Water Jet Blast Apparatus, by Prof. Herbert E. Metcalf.
New Radio graph chart which solves
all calculations in wave-length, in-
ductance and capacity, by E. M.
Tingley.

Harmonics—Part II, by Prof. F.
E. Austin.

ELECTRICAL EXPERIMENTER

When Blucher was standing on the Lon-
ton Tower looking over the vast city he
exclaimed: "What plunder! A German
availing himself of our own errors to
claim: "What an opportunity for ruthless-
ness!" There are hundreds of targets here
that would prove almost impossible to miss
for any skilful aviator—New York, New
York even at night lends itself extraordinarily
well towards such an exploit. If you have
ever been up on a 200 foot ladder over
New York on a dark night, you will
have found that it is never absolutely dark,
the two rivers always providing a certain
illumination and moonlight. A skilful
aviator would find it difficult to miss his objects.

There are, first of all, the hundreds of
docks and the bridges which, besides the
railroad stations and numerous other points so large that a skilful aviator
could hardly fail to hit his objectives when
dropping low. And we have no aerial defenses
at the present time worth speaking about.
We have heard about anti-aircraft guns
being emplaced, but we have seen nothing
far. We have not a large defending aero-
plane fleet as yet, and unless we organize
one soon, we will be practically helpless against
an aerial attack. For instance, there is
certainly a great number of some industries of course in having defending aero-
planes stationed about Long Island, who
are giving battle and fighting as they are sighted. Thise we consider of
paramount importance, and we will in time
no doubt have such a defense. It cer-

The writer desires to advance an idea
here, which, while it may not be an all-
engagingly certain to prove to be an impor-
tant factor if a raid is ever planned upon
our cities.

His idea is to throw a cordon of sensi-
tive submerged microphone buoys about
the central station which might be the
Brooklyn Navy Yard. Three to five hun-
dred of such buoys would effectively
help us to listen in for submarines at the cen-
(Continued on page 192)
The Story of A Pound of Coal

Explaining the enormous losses occurring when a pound of coal is burned under a boiler, the steam generated used to run a steam engine, and this in turn caused to drive a dynamo supplying electricity for lighting.

Did you ever stop to consider how much of the energy present in a pound of coal is actually converted into electrical energy, even in the best power plants of to-day? In a few words it is this—that out of every pound of coal burned in a steam boiler in an electric power station we only succeed in converting about one-half of one per cent of the total energy in that pound of coal into radiant light! The average person believes that in this so-called "electrical use" we have reached well-nigh perfection, but the above figure illustrates vividly that the electrical and steam engineers have many problems yet in front of them before anything like real efficiency is attained in converting the energy in coal to electric light, or for that matter into electrical energy with which to feed the lamps and other apparatus. For the largest and most highly developed steam-electric plants of to-day do not realize an over-all efficiency of much above ten per cent.

This figure of ten per cent represents the ratio between the coal burned in the boilers and the current delivered by the dynamos to the bus-bars, and shows that what most persons believe to be a wonderful and highly efficient electric power generating station is really throwing away about 90 per cent of the energy in the coal it buys. A modern water-power electric generating station may show a gross efficiency of as high as 98 per cent; therefore there is something radically wrong with our coal-burning methods, beyond the shadow of a doubt. Several well-known inventors have ventured to design a different type of apparatus for developing electrical energy direct from coal, but so far no commercially successful method has been perfected. Even Edison has tried his hand at perfecting such a machine, but so far we have not advanced beyond the periphery of 1 pound of pure water 1 degree Fahrenheit, at or near its maximum density, 39.1 degrees Fahrenheit. One B.T.U. is also equivalent to 778 foot pounds of energy, or 1 B.T.U. per hour = 0.000293 kilowatt-hour, also 1000 B.T.U. per hour = .293 K.W. hour. Having this quantity in mind the per cent loss in each apparatus is readily judged as we progress from right to left or reference to the following table prepared by Mr. Stott gives these percentages directly.

Thus we see where the energy in the pound of coal goes to before it finally reaches the switch-board bus-bars. In other words, starting with 100 per cent of energy in the coal when placed in the fire-box, we eventually throw away nearly 90 per cent of this energy, or to be exact 89.7 per cent, and deliver to the electrical system only 10.3 per cent of the power we started with, when we lighted the fire in the boiler.

If we operate electric motors from this electrical energy we fare quite well, as the motor has an efficiency of from 85 to 90 per cent or more, depending upon the size. That is, the motor converts 90 per cent of the electrical energy put into it into mechanical power at the pulley. But in converting the electrical energy into radiant light we find that the most efficient of all incandescent filament lamps—the tungsten lamp—only realizes about 5 per cent efficiency, and requires about 1 watt per candle.

(Continued on page 198)
CUTTING 260 LAYERS OF CLOTH AT ONCE.

The garment cutting department of the Atlantic division of the Red Cross has its own little trials. Its particular job is to supply with garments cut out and assembled all the Red Cross chapters in New Jersey, New York and Connecticut as fast as those chapters send in calls for materials. And that is no easy task.

The amount of work required to keep up with the demand is enormous. Recently, in one week, more than 65,000 yards of material were cut into 1,600 dozen garments. To accomplish this the Red Cross has turned itself into a factory, and highly trained workers manipulating the most efficient kinds of machines make that output possible.

Between the work-room partitions are tables ninety feet long, over which on trolleys suspended from the ceiling run various electric machines. One of them is for spreading the material, one for making stencils as long as the table and another for actual cutting.

This last has to be guided with tireless care. It is fitted with a revolving knife razor so sharp that it will cut thru 260 layers of heavy material as easily as thru one. A single slip, therefore, on the worker's part, an instant's inattention, would be a costly thing.

The stenciling machines, which have little wheels with red hot points for burning holes in paper, are time savers. In order that there shall be the least possible waste of material the patterns have to be fitted into each other with the intricacy of a clever picture puzzle. To do this down the length of a ninety foot table takes an expert worker over four hours, where once a stencil has been cut an untrained person can mark the same amount of material in fifteen minutes.

The department, which has been in operation only a short time, has until lately confined itself to cutting hospital garments. Recently for the first time it undertook refugee garments as well. After devoting its energies exclusively to these for six days, it had on hand a sufficient stock of garments of nineteen varieties and forty-seven sizes to meet any orders which the chapters may send in.

MECHANICAL EQUIVALENT OF LIGHT.

A mathematical equation has been obtained by the U. S. Bureau of Standards for the visibility curve of the average eye. This equation was combined with Planck's equation of spectral radiation of a black body. Using the radiation constants of a black body and its brightness at various temperatures, it was possible to obtain the luminous equivalent of radiation or the so-called mechanical equivalent of light.

Independent checks of this constant were obtained by measurements upon an incandescent lamp of known candle-power, using a special physical photometer. The data obtained by various methods indicated that the mechanical equivalent of light is of the order of 1 lumen = 0.0016 watt of luminous flux of maximum visibility, or 1 lumen = 49 candles.

These data are of much use to-day, so much attention from inventors in the past ten years as that involving some form of street and station indicator adapted for use on trolley or interurban railway cars. After hundreds of such schemes, including everything from wonderful talking machine arrangements up to constantly changing signs, seem to have been thought of by the conscientious inventors striving to solve the problem, but very few of these automatic street announcer schemes have been tried out and few, if any, have found favor with the trolley and railway concerns at all, so it seems.

However, the accompanying patented arrangement recently perfected by Mr. John O. Lough seems to have considerable merit. The invention comprises a suitable enclosure cabinet, inside of which there is supported a revolving drum on the periphery of which there are suspended pivotally a large number of signs, each of which is labeled progressively with the street numbers for a given car route. Just after passing each street an auxiliary electric circuit is closed which operates an electro-magnet placed within the announcer cabinet, this magnet actuating a set of pawls arranged in the manner shown in the drawing herewith. At each impulse of the electro-magnet and pawl system, the drum carrying the various street signs is moved around a short distance, just sufficient to bring the next street sign in position before the opening in the cabinet. An electric bell can be arranged to signal each change of the announcer so that passengers will pay proper attention to the device, altho once it is installed a short time patrons will soon become accustomed to it. We believe Mr. Lough deserves a vote of thanks from a long suffering public, as all that we can hope to learn concerning the name of the next street announced at present is a conglomeration of vowels and consonants that sounds like—BLLWXY?X.

"Violet rays," i.e., the discharge which takes place in a vacuum when the bulb in question is connected to a high frequency coil, can be deflected by means of an electro-magnet.
An Electric "Movie" for Show-_windows

A new type of moving picture machine for office, convention and show window has been brought out by a New York concern. This machine displays pictures which can be readily seen in broad daylight, as well as by night. Its operation is entirely automatic in all its functions. After the reel is projected it is automatically rewound and then displayed again, so that after the machine

and in the opposite direction for rewinding.

A 250-watt Mazda stereopticon lamp, with

is arranged and started it will continuously operate for an indefinite period without any further attention.

The outfit consists of two separate parts, the moving picture machine and miniature theater in which the pictures are displayed. The moving picture machine is operated by a standard type universal motor, which will operate on either direct or alternating current. Two horizontal discs carry the film which passes in one direction for projection concentrated filament, furnishes the light, which is automatically extinguished when the machine stops and during the process of rewinding.

The machine is equipped with two automatic safety switches, which are provided for in case the film breaks, in which event the machine stops and the light goes out, if this occurs while projecting; in case it happens while rewinding, the machine simply stops, the light being out.

Here it strikes a mirror set at an angle of 45 degrees, and is reflected upwards onto a screen, set on what would be termed a stage. Another 45-degree mirror reflects an image of the screen, making the picture appear to the audience to come from a screen on the rear wall of the theater.

Standard non-inflammable films in lengths of 50 to 500 feet can be exhibited. The outfit draws 2½ amperes and is approved by the National Board of Fire Underwriters.

THOSE "ODD" ELECTRICAL PHOTOS.
The accompanying photo shows a really novel electrical effect—the kind we are after and stand ready to pay $1.00 cash each for. Say, readers, we really wonder if you have ever read the notice publish

on the title page of the "Question Box" in every issue for the past six months. This notice to all readers, whether regular subscribers or not, says that $1.00 will be paid for any photo we can use—but they should be "odd ones," like that below.

Now, readers, and there are several hun-
dred thousand of you, for the love of Horse-thief Pete, get out that kodak or plate camera. Dust her off and go shoot-

ing for that "odd photo." We know it's there, but as we can't travel all over the United States and thru foreign climes to ferret out these interesting subjects, we put it up to you to get these photographs for us.

The present photo is a beautiful one and it shows the "ladder sparks" produced by the amateur photographer—Mr. Kenneth Strickfaden's—eighteen-inch spark coil in full activity. Mr. Strickfaden took this fine photo, the original being of ordinary pocket kodak size, or 3½ by 5½ inches.

WASHINGTON STATE COLLEGE TO HAVE SIGNAL CLASSES.

Washington State College, Pullman, Wash., will heed the call of the government for 15,000 trained men for the signal corps and will attempt to provide between 50 and 100 men qualified for this service in as short a space of time as is possible. Classes in signal corps work will be started immedi-
ately. Training will be given in the interna-
tional wireless code, a speed of 20 words a minute in sending or receiving being re-
quired before the completion of the course. The code to be taught is used through the signal corps service in wireless, wigwag and buzzer signaling.

The United States Government buys about 2,000,000 incandescent globes yearly.

LIGHTING THE AUTO RADITATOR FLAG.

An electric lamp for illuminating a radia-
tor flag, which may also be used as a porta-
ble inspection lamp, has been developed by a New York concern. The outfit includes a silk flag, a silver-plated parabolic reflector and a rubber-finished rolled steel bracket. It can be operated at small cost from the automobile lighting and starting battery. Where no storage battery is available, dry cells can be used.
Milestones in the Life of Thomas A. Edison

THOMAS A. EDISON, leader in American scientific thought, has accomplished so many wonders in his lifetime that to enumerate them would seem to require a lengthy article, but the following tabloid outline of the scientific milestones in his wonderful career give a succinct and comprehensive survey of his activities. This paper was presented before a meeting of the San Francisco Development League by Frank D. Fagan.

1847
Born February 11th, at Milan, Ohio.

1857
Started chemical laboratory in cellar of his home.

1859
Became newsboy and "candy butcher" on trains of Grand Trunk Railway, running between Port Huron and Detroit.

1862
Printed and published a newspaper, The Weekly Herald, on the train. The first newspaper ever printed on a moving train.

1862
Saved from death young son of J. U. Mackenzie, station agent of Mount Clemens, Mich. In gratitude, the father taught Edison telegraphy.

1863
Spent nearly five arduous years as a telegraph operator in various cities of the Central Western States, always studying and experimenting to improve the apparatus.

1868
Entered office of Western Union in Boston as operator.

1868
Made his first patent invention, electrical vote recorder. The application for patent was signed October 11, 1868.

NEW MONUMENT MARKS PLACE WHERE TELEPHONE WAS CONCEIVED.

Dr. Alexander Graham Bell, inventor of the telephone, tells us that Brantford, Ontario, Canada, is right in claiming the invention of the telephone. The invention, according to Dr. Bell, was conceived in Brantford in 1874, forty-four years ago, and born in Boston in 1875. Dr. Bell was present at the unveiling ceremony as well as leading telephone men from the United States and Canada. The great achievement of the telephone invention by Prof. Bell has thus been commemorated by the erection of a magnificent granite and bronze memorial, which is located in one of the city's parks.

1876 to 1877
Invented the carbon telephone transmitter, which made telephony a commercial art, and which was combined in 1914 with his later invention, the phonograph, to form the telescribe.

1877
Invented the phonograph. Patent was issued by United States Patent Office within two months after application, without a single reference.

1879
Invented incandescent electric lamp. The invention was perfected October 21, 1879, on which day the first lamp embodying the principles of the modern incandescent lamp was put in circuit and maintained its incandescence for over 40 hours.

1879
Invented radical improvements in construction of dynamo-electric machines, making them suitable for generators for systems of distribution of current for light, heat and power.

1880 to 1883
Established first commercial incandescent lamp factory at Harrison, N. J.

1882
Invented and installed life-sized electric railway for freight and passengers at Menlo Park, N. J.

1891
September 4, commenced operation of first commercial central station in New York City for distribution of electric current for light, power and heat.

1891
Invented the motion picture camera. By the invention of this mechanism, with the continuous tape-like film originated by Edison, it became possible to take and reproduce motion pictures as we have them at this day.

1890 to 1910
This period covers the work resulting in the invention of the Edison Alkaline Storage Battery, and its commercial introduction in 1914.

1914
Edison, being the largest individual user in the United States of carbolic acid (for making phonograph records), found himself in danger of being compelled to close his factory by reason of the embargo placed on exportation by England and Germany, the sources of supply, carbolic acid being used in making explosives. Edison devised a plan for making carbolic acid synthetically, set gangs of men working 24 hours a day to build a plant, and on the 18th day was making the acid. Within four weeks plant could turn out a ton a day.

On the night of December 9th, Edison's (Continued on page 194)
Peeling Tomatoes by Electricity and Reclaiming Waste

In the operation of canning tomatoes and other vegetables it has hitherto been practically impossible to remove the skins without first heating or partially cooking. However, a down-East genius, one William H. Chapman, of Portland, Maine, has found that if the skin of the tomato is punctured by electric sparks sufficiently near together, the effect will be to form small holes in the skin which loosen it from the pulp, so that it may be readily peeled or stripped off. He has obtained a U. S. patent on the scheme. The heat from the spark apparently has the effect, besides puncturing holes in the skin, to expand the air inside of the skin where the spark passes thru and so detach the skin from the pulp.

A comb conductor charged with a high voltage alternating electricity is located adjacent to the tomato and the apparatus is so formed and manipulated that all portions of the skin are presented to the discharging points.

In the apparatus illustrated for carrying out the process in a simple manner, the tomato is stuck on a forked support or spindle, journaled in the base of the device and slowly rotated by a suitable pulley and belt connected with an electric motor.

As here shown, the comb is connected with an alternating current line with a commercial current of 110 volts connected with the primary of a transformer. Thru the transformer, the voltage is raised to about 12,000 volts, capable of producing a spark of nearly one-half inch in length. The connection from the conductor to the transformer is made thru the carriage by means of a wire. A handle is provided for sliding the carriage back and forth to the tomato being operated upon. The holder on which the tomato is held is formed of metal or other conductor and is thoroly connected to earth. The number of alternations of the usual commercial circuit are 60 per second and the sparks will be emitted from each of the points substantially at this rate. The tomato may thus be rotated with considerable speed and the skin will be thoroly perforated with holes. In applying this process to a canning factory, much more elaborate and rapid acting mechanism would be used, but that illustrated is perfectly capable of carrying out the process.

While this process is primarily designed to be used for tomatoes, it is capable of being used with any fruits or vegetables with thin, non-conducting skins, as plums, apples, peaches, corn, etc. The body of the tomato is not affected by the current used.

Most important of all, a recent bulletin of the U. S. Department of Agriculture brings the fact that vast quantities of tomato refuse accumulating each year at tomato-pulping factories can be reduced to two products—viz, fixt oil and meal—both of which may be made commercially useful. The oil from the seeds is suitable for use as an edible oil or as a soap oil, and by proper treatment can be made useful as a drying oil for paint and varnish. The meal has valuable qualities as stock feed. The department urges the establishment of reducing plants and the adoption of a cooperative plan of manufacture in the regions where tomatoes are extensively used to make catsups and soups, the seeds and skins being at present discarded as useless. The utilization of tomato waste seems to have made much more progress in Italy than elsewhere.

A TROPICAL LINE PARTY.

Seeing in the December issue a photo of a telegraph line party in the far North, I thought that a photo of a line party in the tropics might be of sufficient interest to send to you.

The boys shown in the picture are recruited from their native villages in the Territory of Papua, and sign to work for the Government for three years at the rate of 10 shillings per month and found ($2.50), and are placed under the charge of a white lineman who instructs them in the various arts of "slinging lines"; from there they pass to fitting instruments, locating faults, etc.

After the three years are up they are sent back to their homes for a spell and, should they desire they sign again for three years, this time as operators, their wages being raised to 15 shillings a month and found.

The telephone exchange is a magneto service of a hundred lines, with several long-distance lines to plantations, the longest being 34 miles from Port Moresby.

The boys (Meros) are taught English at the Mission school during their second term: otherwise to ask for, say call 26, would sound somewhat like this—"Rua-Huey—Toura Toi."—JOHN J. BOILEAU.
Make Way for the Lady Engineers

IT'S just a bit difficult to say who the first lady engineer was. The number of women—other than typists, stenographers and clerks—employed in the engineering department of one of the largest electrical manufacturing companies has been gradually increasing in the past four years. Most of these young women who have entered the realm of real, applied engineering were college graduates to whom school teaching was evidently not the one and only resort. All of them were at first assigned to one group. Requests for translating, reference work and computations were made on this group. Later, when the telephone transmission branch started talking in terms of impedance instead of resistance, and doing other queer things, the demand for computresses in that particular branch became so great that several girls were definitely assigned to transmission work as calculators. From this beginning it was easy enough to present the girls to the various measuring devices.

Girls were tried at the calling end of telephone transmission tests, but the voice strain was found to be too great, so now their activities in this particular field are limited to listening—listening to nursery rhymes and the like for hours upon hours!

In addition to computing and making electrical measurements and transmission tests, girls are also employed on drafting and on follow-up work on jobs placed in the Model Shop.

The other laboratories of this electric company were quick to realize the value of women for certain kinds of work, so they, too, began to cast around for suitable representatives of the female of the species. In the Physical Laboratory the experimental work on telephone switchboard lamps and on filaments in general required deft fingers as well as agile brains. Here, then, was an opportunity not only for girls with some technical training, but also for those with skill in light manufacturing processes. Thus we see the entrance of girls into the realm of the breakdown demand in the Physical Laboratory as anywhere else—so the demand for mathematicians went up a few notches more.

Who Said the Women do Not Take Up Such Studies as Electrical Engineering? They're All Wrong, for Here Is Evidence to Show That Women Are Holding Their Own in a Large Research Laboratory.

Here Again We Have the Women Technicians in the Chemical Laboratory of One of the Largest Electrical Concerns. As the War Goes on We May Expect to See More and More Women in Engineering Lines.

Recently there has been a great demand for special condensers and fuses which, for various reasons, must be manufactured under laboratory conditions. This work does not of necessity call for operatives with more than average education, but it does mean the presence in the laboratory of a fairly large number of women. If any of them show special aptitude or inclination, it is a fairly easy problem to acquaint them with the workings of the simpler measuring devices and to instruct them in the making of various mechanical tests on apparatus. It has been found that women have a distinct aptitude for mathematical and engineering processes. They operate Wheatstone bridges, planimeters and slide rules with speed and precision.—Photos Western Electric Co.

ELECTRIC ORANGES.

Prof. J. A. Fleming, in a lecture at the Royal Institution, London, England, to a juvenile audience, said that not many boys and girls knew that when they cut an orange with a steel knife and a silver fork a current of electricity past thru their hands. The acid in the orange acted on the steel, and the orange acted as a voltaic cell.

X-RAY DETECTS TUBERCULOSIS.

Electricity is playing an ever increasing part in the examination of troops for medical defects. The X-ray has been employed recently in detecting whether certain New York troops have tuberculosis. Of the first 600 men examined by this means twenty-two were found to be so infected as to disqualify them for military service.
An American Ace

An unprecedented triumph! And rightfully may it be said so, with a smack of the old melodrama, Biff! Bang! of shot and shell this truly patriotic war play has arrived into its own.

The play is centered about a number of thrilling scene effects of which probably the most realistic is that where our boys go "over the top."

The story of the play is somewhat slow in action in the first part and this could stand a little speeding up. It is not until the second act that it really struck its stride and after that the action was fast and exciting.

James L. Crane was a thru and thru "pachist" in the first part until, the wavering spark of patriotism answered the call and from then on he was out to get the "Hun."

Somewhere on the battleline the Germans abandon a Belgian village, leaving behind them desolation, destruction and two spies "He" and "She" to communicate information that will enable them (the Germans) to "gaz" the Americans without warning.

The Americans arrive and take the village but are rather suspicious of the two spies and when the man is seen telephoning information to the enemy by a little "Belgian Miss," the heroine, the female spy gives an alarm so as to ward off suspicion from herself and incidentally enable her to carry on the nefarious work. The hero, who is now an "American Ace," naturally falls in love with the "little Miss" and a quaint courtship is interwoven amidst all the cannons' roar.

The villainess eventually meets her Waterloo and the final scene shows the lovers united in each others' arms atop a church tower, while down below the Americans are driving back the "Boches" with fixed bayonets.

Chief amongst the thrillers is an exciting battle in the clouds when the "American Ace" goes up and down three German planes. So realistically is this scene arranged that the spectators imagine themselves up in another plane looking on at the duels taking place. Another tense moment comes when the German planes bomb the town with aerial torpedoes, when with a crash and a bang buildings tumble down and with all the debris and plaster flying around, it might well be best to bring your own "dugout" and gas helmet with you.

THE NEW YORK MEETING OF THE A. I. E. E.

The April meeting of the American Institute of Electrical Engineers was held on the evening of April twelfth and was attended by a large number of the engineering fraternity, amongst whom were several prominent persons, including many members in uniform who are doing their all for the U. S. A.

Two important papers were presented: "A physical Conception of the Operation of the Single-Phase Induction Motor," by B. G. Lamme, and "No-Load Conditions of Single-Phase Induction Motors and Phase Converters," by R. E. Hellmuth.

Mr. Lamme read his own paper, which covered a new method of studying the actions of a single-phase induction motor, a method which he had found to be very convenient from an educational standpoint.

Starting with the assumption that a single-phase alternating magnetic field may be considered as being made up of two constant fields, each of half the peak value of the single-phase field and rotating at uniform speed in opposite directions, then if the single-phase flux distribution is of sine shape and varies sinusoidally in value, it may be replaced, or represented, by two sine-shaped fields of constant value rotating in opposite directions.

The full load conditions are next considered. A comparison is made between a two-motor unit, consisting of two similar poly-phase motors coupled together and connected for opposite rotation, and the straight single-phase induction motor. Several diagrams were shown, as well as some interesting curve charts. The paper contained a considerable amount of test data, which served to illustrate the principles and actions described in the paper.

Mr. Hellmuth was unable to attend, much to the regret of those present, and his paper was read by Mr. A. M. Dudley. The paper showed methods and derived formulas for the determination of the fields, the stator and rotor magnetizing currents, and the tertiary voltages for phase-converters and single-phase induction motors at no-load.

The treatment of the subject is uniformly based on fundamental laws. A number of different considerations are used for the various cases illustrated to assist in the solution of the problems; however, all are based on simple facts.

AN ELECTRICAL EXPERIMENTER

July, 1918

It's Hard to Tell the Imitation Soldier from the Real One These Days, Especially When the Signal Corps Members of "An American Ace," a Recent Stage Success, Start Acting.

It is quite interesting to note the faithful military atmosphere that is truthfully kept, especially when the American boys take the town. Entering in a dignified and businesslike manner they proceed to lay out plans, while the "Signal Corps" troops establish their lines of communication, switchboards, etc. A close-up view herewith shows the general staff and the chief officer issuing orders for the strengthening of various portions of the lines.

The true fire-works commence when the boys go "over the top," then Cain lets loose and by the amount of deafening reports it sounds like the Great Spring Drive transplant-ed to the United States. To your "dugouts," boys, when this big thrill comes off! Nevertheless the audience took it in great shape and it was greeted with a storm of applause.

All of the members of the cast did well and special mention might be made of the excellent hero rôle as played by Mr. Crane, the equally admirable heroine, Miss Marion Coakley, who with her sweetness and charm is a "comer"; Miss Sue MacNamara was a charming villainess.—George Holmes.

An electric magnet weighing only seven pounds that will lift fifteen times its own weight has recently been invented. It is intended for use in machine shops.

"Don't Be Impatient, Bill. You're Going to Feel It,"—Irish in the Columbian Dispatch.
A New Electric Recording Compass

By EUGENE STAEGEMANN, Assoc. A. I. E. E.,—Prof. of Mathematics and Mechanics, Vocational High School, New Britain, Conn.

The new electric-recording compass device, here illustrated, is one which nautical experts have proclaimed to be a great advancement in maritime appliances. This electric Recording Compass was invented by Dr. C. L. Jaeger of Mahwah, N. J., to supply vessels with a device which would record a permanent record of the entire route covered, to the fact that the Nautilus, Jules Verne's master creation in "Twenty Thousand Leagues Under the Sea," had every conceivable type of apparatus and appliance aboard except a recording compass.

To remedy this serious defect he began the first experiments. It is perhaps unnecessary to say that he encountered great opposition, but finally, after five years of ceaseless toil, in an attic, and great sacrifices a crude working model was particularly gratified by the results. Charged with this encouragement, Dr. Jaeger endeavored to market the invention, but met with violent opposition, not on the part of the ship owners who appeared (Continued on page 202)

Three Views of the Jaeger Electric Recording Compass, a Number of Which Are Being Built for the Navy Department. At Left—The Recording Compass With Dial Removed; At Center—Compass Complete With Spark Recorder and Chart; Right—Electrical Instruments Used With Recording Compass.

Dr. Jaeger began his first series of experiments on his recording compass about 1885, in the days when the electrical experts of the world were classified in two ways—those who knew Ohm's Law and those who didn't. He jokingly attributes his endeavor to supply vessels with a device which would record a permanent record of the entire route covered, to the fact that the Nautilus, Jules Verne's master creation in "Twenty Thousand Leagues Under the Sea," had every conceivable type of apparatus and appliance aboard except a recording compass.

An Actual Compass Record of a Cruise Up Long Island Sound Taken On Board Dr. Jaeger's Yacht. Each Angular Division Represents a Time Period of One Hour.
Rapid strides have been made during the last five years in the advancement of practically all branches of science. Especially is this true of Radium, in its various forms, and its application to relieve humanity of much of its suffering.

Early in 1912, from information that reached the U. S. Bureau of Mines, it became evident that large quantities of valuable Radium bearing ore from Colorado was being exported to foreign countries for purposes of manufacture, and undoubtedly a part of the manufactured product was being reshipped to this country.

In view of the fact that the largest known supplies of Radium bearing ore in the world was centered in the States of Colorado and Utah and on public lands of the U. S., the Bureau of Mines decided to investigate the prospect and to ascertain whether these valuable tracts could not be acquired by the U. S. and the Radium extracted under Government supervision, to be supplied at cost to the hospitals of the Army, Navy and Public Health Service.

At that time no appropriation for such work was available. However, the Bureau learned that Dr. Howard A. Kelly of Baltimore, Md., and Dr. James Douglas, of New York City, were deeply interested in the production of Radium for use in two hospitals with which they were closely associated. The suggestion was made that they form a Radium Institute, to work up the ore and keep the Radium for the use of our own people. The mines were inspected and after extensive preliminary surveys, the National Radium Institute was founded. The agreements being that the Institute was to receive the Radium from the owners of the mines on a 15 per cent royalty basis, with the stipulation that the Institute would return the uranium and vanadium contents of the ore to the company.

A considerable personnel was instituted at the radium plant and a number of large buildings erected and put in operation. The average capacity of the plant at present is about 3½ tons of ore per day, and a considerable amount of the element has been extracted up to the present time. Beyond any doubt, the amount of Radium in nature is exceedingly small. Therefore this fact, in itself, is an important factor bearing on its value today. Altho quicker and better processes are used for its extraction now than, say, four or five years ago its market value will not decrease to any extent.

To total amount of Radium element at present in the world extracted from the ore is said to be 61 grams of which amount 16 grams is held by various doctors and institutions in the United States. Dr. Howard Kelly of Baltimore has about 6 grams, the Memorial Hospital of New York has 3½ grams, and the other 6½ grams are distributed in the U. S. The remaining 45 grams are in various other countries.

It has been estimated that if all the radioactive ores were mined they would not produce more than a total of 400 grams of refined Radium element; therefore the high cost of Radium—at present $120,000 a gram, or $120,00 a milli-gram.

Radium is a chemical element, belonging to the group of metals, but unlike most other elements, it is not extraordinarily stable. It transforms itself at a measurable rate into another substance called Radium emanation. The rate of transformation, is so slow, however, that about 1700 years would be required for half a given quantity of Radium to disappear.

The emanation is a chemically inert gas, and it, too, transforms itself into a third substance called Radium A, but this is not all. Radium A transforms itself into Radium B, and Radium B into Radium C, this forming a series or chain of substances all related to each other.

None of the above substances is a gas except the emanation Radium A; B and C deposit themselves on anything and everything that comes in contact with them, including the walls of the vessel that contains the emanation.

Radium may be used in the treatment of disease either in the form of Radium salts or Radium emanation, the therapeutic effects being identical.

This Radium emanation may be collected in glass tubes or metal containers, and used with appropriate screens, as Radium salts themselves, or dissolved in distilled water or in a weak saline (salt) solution, and administered by drinking or injection. Emanation applicators are often of the greatest value in treatment of malignant...
growth, as in them it is possible to concentrate the activity per unit area to a very high degree. The 100 cc. of 1% solution of the tubes of Radium sulfit oxide generally used, measure 4 cm. in length and 0.2 cm. in diameter. It is quite easy to make an emanation tube of equal activity measuring only 0.5 cm. in length by 0.05 cm. in diameter.

Such a tube can be enclosed in an iridium pointed platinum needle with walls of 0.3 mm., in thickness, thus forming a very small but extremely powerful apparatus for the treatment of nodules in tongue, palate, breast or other organs.

Radium emanation falls to half-strength in 3.8 days, losing 10% per cent of its initial activity within the first twenty-four hours. The duration of an exposure rarely exceeds twenty-four hours, and if it is decided to give a treatment for that time with a radium emanation apparatus, of say 100 mg. strength, the apparatus leaves the laboratory with an initial activity of 109 mg. 110 mg. At the end of 24 hours its activity will have fallen to 92 to 93 mg., so that its mean activity throughout that period will have been approximately that of 100 mg.

The general principle of the operation of the apparatus necessary to fill the small capillary tubes with the Radium emanation is as follows:

Fig. 3 represents the arrangement of the glass tubes and reservoirs. The bulb A contains the Radium salt dissolved in water. Radium in solution continually decomposes the water into hydrogen and oxygen, and at the same time transforms itself into the emanation, which is set free. The total volume of the hydrogen and oxygen amounts to more than two hundred thousand times that of the emanation at the same pressure and temperature. In addition to the oxygen and hydrogen and emanation, a small quantity of helium appears, and also traces of other gases. On account of its radio-active transformation, the exact proportion between the quantity of emanation and the gases with which it is mixed, depends on the length of time the gases are allowed to accumulate.

The mixture of gases collects in A and the tube B, and also if the passage is open, in the reservoir C. Allowing the gases to collect in C, apparently increases the efficiency. The tube B is considerably longer than 76 cm., so that air may be admitted into C, if desired, without its finding its way up into the Radium solution. The trap at B protects against mercury spurtling up into the Radium solution, should some of the glass apparatus break. An ordinary water aspirator with suitable stop-cocks controls the flow of mercury between the reservoir and trap. By admitting the air into D, the mercury rises in C, pushing the mixture of gases thru the mercury trap E, into the tubes F. The mercury in the trap E holds back all but a very small quantity of the water vapor. The tubes F contain a copper wire, slightly oxidized, phosphor-pentoxide and potassium hydroxide. Altogether the mixture of gases in F is more than 75 cm. long. The whole is set in a base of concrete so as to make it impervious to all shocks which might damage the delicate apparatus.

**LET ELECTRICITY WIND YOUR PHONOGRAPH.**

A new electric motor winder adopted for attachment to any style phonograph.

Winds any Phonograph by Electricity. Attached in place of Winding Handle.

**Fig. 3, 4, 5**

ELECTRICAL EXPERIMENTER

A new electric motor winder adopted for attachment to any style phonograph.

so as to still retain the spring motor drive, which has so far proven the most satisfactory, has been invented by Joseph W. Jones, who originated the Jones Speedometer of world fame, the disc record which is the foundation of talking machine success, the taximeter, the taxi-cab meter. Any motor winder uses no current, except when actually winding up the spring.

In case of failure of lighting current or that current is available, the winder may be instantly detached and the old-style crank used.

In case the user moves to a district where current is not suitable to his motor winder, this may be exchanged by the dealer in that locality.

The use of the winder as to the mechanism is novel, as the power is applied when you use the winder.

This useful device is said to operate one month for one cent's worth of electricity. It is easily and quickly attached in place of winding crank, being applied or detached with the use of only a screw-driver in less than a minute by anyone. The winder will automatically wind your talking machine and stop when it is sufficiently wound. By pressing down the push button on top of the motor it will wind at any time, and the makers recommend doing this before playing each record. The push button cannot be prest down until the motor has been attached to both the phonograph and electric current.

**VISIBILITY OF RADIATION OF THE AVERAGE EYE.**

It is important to know how the eye responds to lights of different colors but of the same energy value. Only during the past year the investigation of the relative sensibility of the average eye to light of different colors was completed. The visibility of radiation of 130 subjects was determined, and various applications were made of these data to problems in radiometry.

A solution of salts was prepared which has a transmission curve coinciding very closely with the visibility curve of the average eye. Using a cell containing this solution, interposed between a thermopile and a source of light, further tests were made of this combination as a physical photometer. Using these visibility data, the following computation shows that the eye is so sensitive that the minimum perceptible light is probably less than one billionth erg.
Popular Astronomy

DARK STARS

By ISABEL M. LEWIS
Of the U. S. Naval Observatory

WHAT a vacation is to our tired bodies, Stellar Space should be to our minds. In the entire realm of Science there is nothing more elevating, nothing more ennobling than the study of Astronomy. Infinite space holds forth so many wonders and enlarges our mental horizon so enormously that modern man or woman must consider his or her education incomplete without at least a rudimentary knowledge of the wondrous world spread out in space all around us.

Astronomy is considered by many a dry, uninteresting science, good only for "highbrows." The opposite is the case. It is neither dry nor difficult of understanding, and once the mind becomes interested in its study, an entirely new and beautiful world is opened to it.

There is nothing more refreshing, nothing more satisfying to our minds than cutting loose for a few hours from our humdrum existence and delving into the boundless ether, where time and space are one, where a million years leave hardly an impression, and where a billion miles are so microscopically small that they are entirely lost in the gulf of infinite space . . .

The writer, an ardent student of astronomy, has always wished to present to our readers popular and non-technical articles on the wonders of the Universe. No connection, however, could be made with competent writers who could present the difficult subject in a manner acceptable to EXPERIMENTER readers.

It affords us considerable satisfaction, therefore, that we are able to present herewith the first of a series of astronomical articles from the pen of Mrs. Isabel M. Lewis. Mrs. Lewis, who is connected with the U. S. Naval Observatory, has written a great many excellent astronomical articles for the New York "Sun," and other newspapers, which have created widespread attention and very favorable comment. Mrs. Lewis, who is a very exact as well as a highly learned writer, has the rare faculty of interpreting difficult and dry subjects in a popular manner, which makes us feel certain that our many readers will welcome her articles enthusiastically.

The ELECTRICAL EXPERIMENTER has furthermore secured exclusive magazine rights for all of Mrs. Lewis' articles for the term of one year. Her articles will not appear in any other scientific magazine. The article in the August issue,—an intensely interesting subject,—will treat on "Gaseous Nebulae."

H. GERNBACK.

THE existence of dark stars and dark nebulous tracts of matter in the heavens is now considered to be an established range of the actual as well as the apparent brightness of the stars has been found to be tremendous. The brilliant Canopus at an immeasurable distance from the earth is conservatively estimated to have fully ten thousand times the light-giving power of the sun, while an excessively faint star of a deep red tinge comparatively close to the solar system possesses but a five to ten thousandth part of the light of our luminaries. The giant star Canopus has at least twenty million times the brightness of the little red dwarf star. There is no reason to believe, moreover, that this extremely faint star marks the lower limit of stellar brightness. A gradual decrease in the light-giving power of this star would place it before many ages in the ranks of extinct suns, cold, dark bodies pursuing their unseen way thru the universe in numbers that we have at present no means of estimating. The evolution of the stars has been traced thru all stages from nebulae to near-extinction and it is logical to assume that the process of evolution is still going on until the star has ceased to shine. Since the energy of a star is finite, it is assumed that the star will exist for a finite interval of time, however great this interval may appear as measured by the standards of man.

Whether or not actual collisions and close approaches of suns may start the evolutionary process anew is at present a matter of conjecture. The sudden flaring-up of temporary stars or Neva is, as they are called, is believed by some to be a visible sign of the rebirth of stars thru collisions or encounters of dark bodies or their passage thru wisps of dark nebulous tracts of matter such as are known to exist in our stellar universe. The true nature of the Novae has not yet been definitely determined, however. So far there are difficulties in the way of all theories advanced to explain these rare phenomena of the heavens, tho their connection in some way with matter previously emitting no light seems a certainty, especially since they occur without exception in the Milky Way, a portion of the heavens where dark absorbing matter of a nebulous nature is intermingled with dense star clouds. The extent of these dark nebulous tracts must be enormous since it is known that their distance is very great and they spread over a space in the heavens that would normally be occupied by many stars. Light, traveling at the rate of 186,000 miles a second, would take many years to traverse from one end to the other of these dark nebulae that emit no light appreciable to the eye.

In some instances dark regions merge into luminous wisps in which one or more stars are frequently enwrapped. The nature of these dark nebulae is extremely low and their total mass very small in comparison to the great volume of space that they fill.

Dark nebulae are presumably nebulae that for some reason never condensed into stellar form, but lost their light and heat while still in nebular condition. In many instances they may be the remains of the material swept up by the stars. The forms of some dark nebulae strikingly resemble those of a number of nebulae shining by their own light. These nebulae doubtless never possessed the conditions essential to a successful entry upon the process of stellar development and drifted on to extinction in their original form.

There are also indications that many stars do not run the full course of evolution from youth to ripe old age but become devoid of light and heat giving power even before the middle-aged period of star life is attained. Such stars are evidently lacking in characteristics essential to the successful development and prolonged maintenance of a photosphere, as the outer illuminating surface of the star is called. A study of
double and multiple star systems reveals these facts. It has been found that on the average one star in every three belongs to a star system of two or more stars revolving around a common center of gravity. Now evidently all stars belonging to the same system and physically connected came into being at the same time, and should be approximately equal in light-giving power provided they do not differ greatly in mass. As a matter of fact, while one member of a double star system is at the height of its development and shines with intense brilliancy, the other is as often as not practically devoid of light, tho in volume, and occasionally in mass, it may surpass its brilliant companion. So feeble luminous are the fainter members of some of these systems that their light is not appreciable to us at all and we only know of their presence by the disturbance they produce in the motion of the brighter companion. Tho some of these stars shine feebly, others appear to be dark in the strictest sense. For some reason they proved to be imperfect radiators and become spent before their time. On the other hand, there are some physically connected systems of stars of which all the members are far advanced in evolution. They appear to have nearly run their allotted course and are nearing extinction. Many such connected systems of stars may be traveling thru the heavens, totally devoid of light, for all we know to the contrary.

There is great diversity in double and multiple star systems and their study forms a most fascinating branch of astronomy and one most fruitful of results. The orbits of the physically connected stars may be inclined at various angles with each other and with the earth and may vary in shape from almost perfect circles to highly eccentric ellipses. The stars themselves are sometimes spherical and sometimes greatly elongated or egg-shaped under the influence of tidal forces acting between the two bodies. They may revolve almost in contact or 3.5 light years apart, or they may be so widely separated that they appear as beautiful little double stars, often of contrasting colors such as red and green or blue and yellow. In some instances a closely revolving pair performing a revolution in a few days around their center of gravity is encircled by a distant companion revolving around the close pair in a period of several hundred years.

A most powerful instrument of research in the study of double stars is the spectroscopic binaries. The great majority of double stars belong to this class.

The spectroscopic consists essentially of a glass prism for separating white light into a band of color of rainbow hue known as the spectrum. Best results are obtained when the light from the star is let in thru a slit placed usually in the focus of the telescope. The ray of composite light coming from the star after passing thru the prism is broken up into rays of various wave lengths, arranged along the visible spectrum from the red thru the yellow, green, blue and indigo in order to the violet, the longest wave lengths being in the red and the shortest in the violet end of the spectrum. Below the red come the infra-red rays and beyond the violet the ultra-violet rays, both invisible to the eye. The spectrum is viewed by the observer at the eye-end of the telescope or is photographed by placing a photographic plate in the same position. The photographed spec-
NEW ELECTRIC HOME MOTOR FOR WOMEN.

People everywhere are rapidly awakening to the fact that electrical labor-saving devices for the home are fast becoming a necessity. This year when labor of all kinds is at a premium, and the general wave of "efficiency" is sweeping the country, the demand for electrical home devices is going to be greater than ever.

The electrical motor here illustrated is easily convertible and with different attachments can be made to churn butter, whip cream, eggs, etc., polish silver, and sharpen knives. It also has a vibrator attachment for massage, with a variety of applicators. It can be made into an electric fan by attaching guard, blades, etc.

The outfit here shown is a churn and mixer motor. This outfit includes the motor with handle, cords, plug, and rheostat, supports for jar with nickel-plated top, which will fit any Mason screw-top jar; also butter churn and cream whipper. With this outfit comes complete instructions for making butter. Its cost is extremely low.

HATCHING "CHICKS" BY ELECTRICITY.

The day of the old, smelly oil-heated chick incubator is rapidly disappearing. Enter the modern electrically heated and controlled incubator of the type here illustrated. And not only do these electric incubators serve the wants of the farmer and chicken fancier, but the army department finds many diversified uses for them. Among other applications, the army medical corps is employing them for developing cultures; the army camps are using them for hatching chicks; and they have hatched almost every kind of egg from that of the silk worm, the smallest, down to the large ostrich egg, besides those of the pigeon, alligator, turkey, duck, swan, emu and the Quail.

The egg chambers are made of California redwood thruout. Double walled, lined with deadening felt and joke board. They are made of good wood, the very best insulating material, and the doors are fitted with double glass with dead air space.

The electric heaters consist of coils of special alloy resistance wire, wound on insulating cores and supported strongly above the eggs in egg chamber. The wire is distributed on the cores properly to give even distribution of heat in the egg chamber.

Regulation is effected by a special regulator operating a simple make and break switch equipped with non-fusible points which is adjusted by a single screw for higher or lower temperatures. No extra magnets or relays are needed to break the small amount of current used in these electric incubators.

Tested thermometers are furnished and an adjustable holder is supplied which holds the thermometer in proper position to be read without opening the door of machine.

The operator can be raised to remove egg tray for turning.

The egg trays are of galvanized steel with reinforced frame and galvanized steel corrugated bottom. Corrugation holds eggs in convenient position for turning. Can be stalled after hatch is finished. The fuse box is removable without opening doors of machine. The hatched chicks can be removed without disturbing eggs on tray.

A small 2 candle-power lamp is installed in the egg chamber which lights up when the regulator turns the heat into the heating coils, and goes out when the heat is turned off. An overhead lamp is the means of telling how the machine is operating. This lamp also enables the operator to read the thermometer no matter how dark the room may be.

These electric incubators are very accurate in their temperature regulation and the average difference in temperature is very low, considering the superior results obtained, as the following figures show:

<table>
<thead>
<tr>
<th>Capacity</th>
<th>Energy Consumed</th>
</tr>
</thead>
<tbody>
<tr>
<td>126 eggs</td>
<td>32 Kilowatt Hours per Hatch.</td>
</tr>
<tr>
<td>252 eggs</td>
<td>36 Kilowatt Hours per Hatch.</td>
</tr>
<tr>
<td>512 eggs</td>
<td>37 Kilowatt Hours per Hatch.</td>
</tr>
<tr>
<td>63 eggs</td>
<td>13 Kilowatt Hours per Hatch.</td>
</tr>
</tbody>
</table>

In extra well built incubator houses these figures will be somewhat lower.

ELECTRIC DRILL HAS PISTOL GRIP AND SWITCH.

The new portable electric drill here illustrated has a pistol grip and trigger switch, and has been designed with special attention to the prevention of breakage of drills when operating the switch.

The control is that of the automatic pistol, one finger operating the trigger switch without the slightest effect on the steadiness of the aim or the support of the tool. There is no releasing of the grip to turn a switch, press a button, push or pull a handle, at the moment the drill breaks thru, allowing the weight to sag on the drill bit. When the drill goes thru the work, you instinctively tighten your grip, retaining control and stopping the drill without breaking the bit.

The casing of the drill is made of aluminum, to reduce the weight. It has a specially designed series, compensated inter-

TEACHING "HER" ELECTRICITY.

By F. C. Davis

"Jack," said his best girl, one night when they were alone in the parlor, "you are so wonderful and you know so much about electricity. Won't you tell me all about it?"

"Sure thing. What do you want to know?"

"Well, what is insulation?"

"Insulation? Now let me see; how will I illustrate that? Let me put on a glove...so...so. I take your hand in mine, so...so, it is now insulated."

"I see. And a conductor?"

"A conductor? Take off your glove, please."

"Why, it's ridicuously simple! What is an amper?"

"That's a little harder to illustrate. It is the power of the electricity. The power -I take your hand- it is the power that makes me do it. You see?"

"Perfectly. But what is a volt?"

"A volt? It is the pressure of the electricity?"

He squeezed her hand tighter.

"That's voltage, electrically speaking."

"Why, everything is so easy-and nice. But what is induction?"

"Hum! That's a poser. Well, I take your hand. The power and the pressure make my heart beat faster; it induces it to speed up."

"How remarkably simple."

"Anything else?"

"Yes. What is resistance?"

"Well-well. If I were a-a-a-to attempt to explain, or kiss you, now, I would meet with resistance, wouldn't I?"

"Well, er-er-er-I don't believe I quite understand. Can't you illustrate that?"

"So he illustrated it; but there was no resistance."

"How wonderful," she fluttered between signs. "Now Jack, dear, what is a short-circuit?"

There was a loud step, and the door burst open and in rushed her father!

"I'll show you what a short-circuit is," he roared as he made for the sofa on which Jack had sat, but luckily sat no more, he having dived thru the window pane with a bang and a rush.

"Some short-circuit," mused Pa, looking over the damage.

The spindle's offset are made to it..."
Experimental Physics

By JOHN J. FURIA, A. B., M. A. (Columbia University)

Lesson 13—Static Electricity

Experiment 74.

If a fountain pen is rubbed on the sleeve of the coat and then brought near some bits of paper (or, better, pith balls), these objects will be found to jump towards the pen. The same effect can also be produced by rubbing a variety of other substances, such as glass and silk, sealing wax and a pencil, paper and rubber (ebonite) and cat's fur, etc. (This experiment was first tried in 600 B.C. by Thales of Miletus, who used amber and silk and the process is called electrification after the Greek word electron, meaning amber.) After so long a time has elapsed since electrification was discovered, even at this late date we do not know much about the nature of electricity, but we do know very well the laws governing its action.

Experiment 75.—Suspend a pith ball by a silk thread as in Fig. 69-a. The stand can be easily made by bending a piece of glass tubing after heating it in a Bunsen flame and attaching the glass base to the sealing wax. Bring the fountain pen (which has been rubbed on the sleeve) near the pith ball. The pith ball will be attracted by the pen and then immediately on touching will be repelled. Evidently the state of the pith ball is changed upon coming in contact with the electrified fountain pen. Rub a glass rod with silk and bring the rod near the pith ball. If we assume the same laws of force as we did in the case of magnetism we find that the behavior of the pith ball is easily accounted for. Referring to Fig. 69, the pith ball in (a) is neutral, i.e., it contains equal amounts of positive and negative charges. As the electrified pen is brought near (let us call its charge negative) by induction the particle near the pen becomes positive and since unlike charges attract, the pith ball is attracted. On coming in contact, however, the strong negative charge on the pen causes the pith ball to become negatively charged. If it is now brought near other objects, it will be repelled. In the case of glass, we find that the pith ball is attracted. Therefore since there is attraction and the pith ball is negative the glass rod must be charged positive, i.e., glass when charged has the opposite charge to the fountain pen when charged. Immediately on contact (Fig. 69-d) the strong positive charge of the glass rod causes the pith ball to be positively charged and repulsion takes place, (Fig. 69-e). It is obvious that just as in the case of magnetism, repulsion is a better test for electrification than attraction, since even a neutral object will be attracted by induction, but only a charged object can be repelled.

Experiment 76.—The electroscope (an instrument for measuring forces of electrification) does not lose its charge. Bring rod up its operation on the principle of repulsion between like electrical charges. Thru a rubber stopper (D) insert a piece of heavy copper wire (C) bent in shape of Fig. 70. Solder a penny (A) to this wire. Cut a small strip of gold leaf (such as is used by sign painters) about 1/6 x 1/2 and place it over the hook of (C). Insert all this in a flask or bottle. This is now a good electroscope and in diagrams is represented as (Fig. 70-b). If now a negatively charged rod (fountain pen) is brought up to the electroscope (Fig. 70-b) the positive of the neutral electroscope is attracted to the penny, leaving an equal amount of negative charge at the gold leaf. Since both sections of the gold leaf have the same charge they will repel each other and move apart; the greater the charge, the greater the force, and hence the further apart they will be forced. However, as soon as the rod is taken away, the positive from the penny will neutralize the negative of the gold and the electroscope will become neutral or discharged.

Experiment 77.—We use two methods of charging the electroscope permanently; by contact and by induction. If we bring a charged rod up to the electroscope and touch the penny with the rod, the gold leaves stay apart permanently and the electroscope is charged. As the negative rod approaches, the positive charge of the electroscope goes to the penny and the negative charge is left at the gold leaves. On contact the positive of the penny goes to the rod and tends to neutralize it, so that on removing the rod only negative electricity is left in the electroscope, i.e., by contact the electroscope is charged with the same charge as the rod used. Charging by induction is a more complicated process, but is important in that the charging rod does not neutralize, i.e., does not lose its charge. Bringing rod up to electroscope as in Fig. 70-b, then without touching the rod to the penny, place the finger on penny (Fig. 70-c). The leaves will be found to collapse, the reason being that the negative of the gold leaves has past thru your body by way of the fingers; the positive staying on the penny because it is held by the negative of the charging rod. Being careful to still hold the rod near the penny take away your finger. Next remove the rod and the electroscope will be charged by induction, since the positive will distribute itself over the instrument as in Fig. 70-d. Note that no charge has been lost by the charging rod. If one is not careful to remove the finger before the rod is removed, the charge left in the electroscope now not being held by the rod also passes thru your body and the electroscope is not charged. By induction it should be noticed that on the electroscope we get a charge opposite to the rod. (If in the above experiments a glass rod is used, a similar but not as marked an effect will result, except that all signs will be reversed, i.e., for positive we will have negative and vice versa.) If we touch a piece of metal to the penny of the electroscope and then touch the metal with a charged rod, we find that the metal allows the charge to pass from the rod to the leaves and we call the metal a conductor. On repeating this experiment, substituting glass, wood, sealing wax or hard rubber for the metal, we find that these substances do not allow the charge to pass. These materials are called insulators or non-conductors. Bring the flannel (with which you have rubbed the sealing wax or fountain pen or else the silk with which you have rubbed the glass rod) up to the electroscope, now test the charge for sign. It is found to have the sign opposite to that of the rod. Furthermore the amount of divergence of the gold leaves shows us that positive and negative electricity always appear simultaneously and in equal amounts, i.e., if we rub glass with silk the glass is charged positively and the silk negatively to the same extent.

Experiment 78.—Let an insulated metal plate be connected to the electroscope by a conductor (Fig. 71-a). Let another similar insulated metal plate be connected by a ground (grounded); charge plate A and note the deflection of the electroscope leaves. Push B toward A and observe that as it gets nearer and nearer the leaves fall gradually, so that we may now add more charge to A (Continued on page 194)
Colonel Carty Receives Edison Medal

D R. JOHN J. CARTY, Colonel in the United States Army Signal Corps and Chief Engineer of the American Telephone and Telegraph Company, has been awarded the Edison Medal in recognition of his services in developing the science and art of telephone engineering.

The medal was presented on Friday evening, May 17, at the annual meeting of the American Institute of Electrical Engineers in the Engineering Societies Building in West 99th Street, New York. Colonel Carty is the eighth American scientist to be honored in this way, the others being Elihu Thompson, Frank J. Sprague, George Westinghouse, William Stanley, Charles F. Brush, Alexander Graham Bell, and Nikola Tesla.

The Edison gold medal was founded in 1904 by the Edison Medal Association, an organization composed of old associates and friends of Thomas A. Edison. It is awarded annually by a committee of 24 members of the American Institute of Electrical Engineers, and was first awarded in 1909, the recipient being Elihu Thompson. It was designed by James Earle Fraser, and bears on its obverse a portrait of Thomas A. Edison, and on its reverse an allegorical conception of "The Genius of Electricity Crowned by Fame."

After Dr. E. W. Rice, Jr., President of the Institute, presented the medal, Colonel Carty in his speech of acceptance, gave credit for the American Telephone achievements to the engineers who have been associated with him in the Bell System and paid a tribute to Major General George O. Squier, Chief Signal Officer of the United States Army, for his work in planning before the United States entered the war, for the rapid mobilization of telephone wires and telephone men for Signal Corps work. Referring to the Bell System engineers, Colonel Carty said:

"We hear a great deal about the German scientist and the wonderful things he has done and has been planning. Many years ago, when German 'Kultur' was interpreted by many to mean German culture, it was suggested to me that we should send to Germany to get some of the Herr doctors to teach us the high science. I always be trained in our work, and that thru them we would undertake to outdistance anything that has been done in Germany. That policy has worked out successfully. The young men who have collaborated with me all these years are graduates of over one hundred universities, all here in America. When at the opening of the war there was a searching of hearts and a census and a taking account of stock, to find out who was loyal and who was to be suspected, I know you will all be pleased to hear that among all of these scientists, and all of these engineers, all working in the Bell System, all over the United States, we were not able to find one single Hun. They were all true Americans to the core."

More than any other man, Colonel Carty is responsible for the development of telephone engineering as it is known to-day, and it is peculiarly fitting that he should receive this new honor at a time when he is working day and night to promote the military use of mediums of communication which have been developed, largely thru his efforts, in time of peace for the advancement of the nation's social, commercial, and industrial activities.

Colonel Carty is well known as the engineer of the great transcontinental telephone line, the longest in the world, and as the engineer who made possible the wireless telephoning over distances up to 5,000 miles. He entered the telephone business when it was in a infancy, and it would be difficult to find a phase of its development which does not bear some imprint of his genius. The technical achievements of Colonel Carty are so numerous as to prevent full recounting. He first pointed out the correct theory of induction between telephone circuits. That was in 1887. In 1888 he developed the bridging bell and pointed out the importance of the bridging principle of telephone construction in obtaining efficient operation of telephone systems and in constructing balanced metallic.
circuit. In 1889 he invented the principle of the best and most generally used common battery system, by which a number of telephone instruments may be simultaneously operated from a single central battery. During this period he also devised important improvements pertaining to switchboard circuits having to do with the "busy test" feature and the connecting in of operators' instruments.

In 1912 the telephone engineering force built up and directed by Colonel Carty had so far overcome the difficulties in the way of underground telephony as to make possible all-underground talking between New York and Washington, and by 1913 they had extended the range of underground telephony to connect Washington and Boston.

The year 1914 witnessed the fruition of the efforts of these engineers to bring transcontinental telephony into existence, and in 1915 Colonel Carty was able to present to the world important developments in wireless telephony, which made possible the hurling of words thru space across the American continent from Washington to Mare Island, California, from Washington to Hawaii, 4,900 miles distant, and from Washington to Paris, bringing Europe and America into speaking distance of each other for the first time.

Then came the threat of war with Germany, and in 1916 Colonel Carty co-operated with the Signal Corps of the Army and with the various departments of the Navy in making arrangements which would ensure the readiness of the Bell Telephone System for military service in case this country did become involved in the great conflict. In 1917 these plans were put into active use with a marvelous degree of success.

Dr. Pupin said that—"Carty's life is filled with romance. He never went to college. At the age of 18, when other boys entered college, he entered the service of the American Bell Telephone Co. and at the age of 28 became Chief Engineer of the great New York Telephone Co. He started with the various apparatus being divided up so as to pack in separate cabinets suitable for transport over mountainous or other rugged country when necessary.

The transmitter is operated on batteries, the operator in the center of the picture being shown in the act of manipulating the key. At the extreme right the receiving set may be seen, with the second operator wearing the head 'phones.

WOMAN RADIO EXPERT TEACHES DRAFT MEN.

One of the most useful war enterprises yet entered by women is that chosen by Miss Elise Owen, a New York girl, who, an expert radio operator herself, has, with the support of the Board of Education and the sanction of the Signal Corps, opened a class in radio operating for men in Class IA of the draft. The class was started late in April and it already has an enrollment of 70 and plans are under way to increase its accommodations and activities. The accompanying photo shows Miss Owen and her Radio Class.

We have consistently advocated the teaching of radio as a patriotic as well as remunerative profession for women. The number of radio students is rapidly increasing at this time. Uncle Sam is sending out every week from 50 to 100 wireless operators from the big Harvard University school which was transferred to the government a year ago as a radio finishing school. It is the only institution of the kind in the country, and its classes have in the aggregate 5,000 ambitious youths. This being a finishing school only those who are able to copy 10 words a minute in the continental code, which is much slower than the Morse, or regular telegraph code, are admitted for the 16 weeks course. To be sent out for service at sea they must be able to receive 22 words a minute, the minimum grading. There are many experts among the teaching force whose speed runs up to 32 words a minute, but beyond that a radio message would be hard to get. From three to six operators are assigned to each ship.

The transmitter involves the use of an open-core transformer resembling a large spark coil, the interrupter being of special design. A quenched spark gap is used. The set is fitted with ammeter and voltmeter to indicate the primary current and voltage supplied the transmitter. A quickly collapsible antenna is carried with the outfit, which can be erected in a few minutes' time.
Small Portable Radio Set for Field Work

Since our entrance into the world conflict, American radio engineers have given considerable attention to the development and improvement of radio apparatus adaptable for various uses in the military service. The essential points to be considered in the making of such radio apparatus suitable for this kind of work are at once, simplicity, efficiency, and rugged construction.

All of the above necessary features have been incorporated in a new radio set designed by a New York radio engineer, Mr. A. B. Cole. The apparatus which he has evolved and which has proven very successful is operated from a battery and for this reason his transmitter is adaptable to various important military maneuvers where other, more cumbersome, apparatus would not adapt itself. The transmitter is shown at Fig. 1. The high tension e.m.f. used for charging the condenser is derived from a specially built spark coil which is enclosed in the case. A new design of independent vibrator is utilized for interrupting the storage battery current necessary to operate the coil. This interrupter is seen in the lower left hand of the panel. An ammeter and volt-meter are interposed in the primary of the induction coil and are used for the purpose of indicating the current and voltage input into the low tension primary circuit. These meters are stationed at the lower right end of the panel. A key is connected in the primary circuit and is also mounted on the panel.

The high tension and oscillatory circuit apparatus consists of a high tension condenser placed within the case; this condenser being charged by the secondary of the spark coil. The condenser is allowed to discharge thru a specially built quenched spark gap and thru the primary of a compactly built oscillation transformer. The gap is enclosed within the cabinet, and a large insulated knob is connected to the movable electrode, which is seen to the right of the independent vibrator. A very small adjustment is necessary to bring the gap to proper operation, as will be evident from the small swing of the pointer. The inductance of the primary oscillation transformer is variable, and it is controlled by a multiple point switch which is located at the upper left-hand corner of the panel, while the multiple point switch to the right of the primary switch is used to control the inductance of the oscillation transformer-

Secondary. A thermo - couple high frequency ammeter is interposed in the ground lead of the open oscillatory circuit, and this meter is located in the upper right hand corner of the panel. The two binding posts placed in the center of the panel are used to connect to the ground and antenna. The telephone switch in the foreground is used to connect the source of power necessary to operate the spark coil, which is generally a six-volt storage battery.

The complete transmitting panel is mounted in a well insulated and ruggedly constructed case and is supplied with a leather carrying belt, the complete equipment being extremely light in weight.

The receiving set accompanying the above transmitting outfit is shown opposite. Altho it is not essential to use this particular receiving set, it was found, however, that most favorable results were obtainable from the particular type of portable receiving apparatus. This set is of the tightly coupled, capacity control type. It comprises a fixed inductive coil wound on a special tube and mounted within the case. Two condensers of the variable, air dielectric type are used entirely for tuning purposes, and these are seen on the upper part of the panel. A crystal detector rectifies the incoming, radio frequency oscillations. This detector is in the lower right hand corner of the panel. A test buzzer is also a part of the equipment, this being used to adjust the detector crystal to maximum sensitivity. The buzzer push button is located in front of the crystal detector stand, while the buzzer is placed at the central left hand portion of the panel. The plug in front of the buzzer is used to connect the telephone receivers, while the plug at the upper center of the panel serves to connect the antenna and ground wires to the receiving set. A partition is provided at the right hand part of the case to accommodate the telephone receivers when the set is not in use. The case of this receiving set is substantially made so as to stand heavy wear and rough use.

Test Wireless Control.

Announcement that satisfactory tests have been made of a military airplane controlled wholly by wireless was made at San Diego, Calif., recently by Flight Instructor N. B. Robbins of the Rockwell field signal corps aviation school. The tests, he said, were made a short time ago, the controls being 12 miles apart.

The new machine, it is announced, carries neither pilot nor observer. It is equipped at present to carry only heavy freight or explosive bombs. The pilot guiding the machine may be in another airplane, in a dirigible or anywhere on the ground. Robbins says that an aviator driving the control in the machine ahead of him may remain fully 15 miles behind. He also says that the machine may be built for one-fourth the cost of a standard military machine. An electrical device for releasing a cargo of bombs is attached to the airplane.

Flight Instructor Robbins is the designer of one of the fastest airplanes ever built in this country, of a very fast motor and of a stabilizer used by the Royal British Flying Corps.
A HOLDER FOR A TUBULAR AUDION.

Those who have tubular Audions know what it is to have to connect the four wires and find them loose again after the receiving is over to put the bulb away in a safe place, so that it will not get broken or tampered with.

In this mind I constructed a holder which has no wires to connect and at the same time makes good connections, and is not apt to fall out of place and break.

The construction of the holder can be seen from the drawings. The rings, B1, B2, B3 and B4 are made of nickel plated brass pipe which can be obtained from any plumber or hardware store. The rings are made about 3/16 or 3/14 inch wide, and 1/4 inch in diameter. As can be seen the rings are held on the tube by sealing wax.

The best way to do this is to make a wooden mold as shown in figures 3 and 4. It will be necessary to get the wax good and hot in order to make it run in the mold. A hot knife blade will help a great deal in pressing the wax into place and smoothing it up afterward.

It is important to put the rings B2 and B3 on first, but connect the filament wires D and F before this. Then put in the other two rings B1 and B4 as shown in figure 1. A short piece of rubber tubing should be put over the wire at K and K1, where the filament wires go under the outside ring.

It will be seen from the drawing that the rings B and B2 are farther apart than B3 and B4. This arrangement makes it impossible to get the bulb connected up backwards as it will only fit one way. The clips are made as shown in figures 1 and 2. No dimensions are given as the builder will make them to suit himself anyway. In cutting out the strips for the clips, which are made of spring brass, do not forget the lug A, figures 1 and 2. The purpose of these is to hold the bulb from falling or sliding downward. The wires should be soldered to the rings before the wax is put in as soldering would melt the wax. The extra filament wire G, can be left short and can be soldered on to lead F, when necessary. It can be seen that this method has many advantages over the regular way, as it is a very good idea to remove the bulb and lock it up when leaving the station, so that it can not be tampered with or broken.

FRENCH BUILD RADIO TO AID AMERICA.

The French navy has just entered the international contest for the honor of building and possessing the most powerful wireless station in the world. In support of its claims that its newly constructed station exceeds all others now in operation, the French navy has just demonstrated its ability to send messages as far as Australia. The stations there, which registered the messages from the new French naval station, were not powerful enough to acknowledge by wireless their receipt, but had the courtesy to reply by ordinary cable that the French wireless communications had been received.

The new French naval wireless station is in reality an acknowledgment of gratitude of the French navy to the United States for its entrance into the war.

The moment America made its formal declaration of war against the enemies of France, the French navy decided to erect immediately a powerful wireless station that would put France into constant and sure touch with America. It was planned also as a very effective safeguard against the submarines for the stream of troop ships and munition convoys which it was realized would soon be headed for France.

A site was accordingly chosen on the French coast, where it was most likely that one of the American naval bases would be established, and from where it would be able to pick up with the greatest degree of certainty distress messages from any American boat that might encounter a submarine.

The metallic pylons of the French station are over 600 feet high. Perfected electrical equipment makes it possible to send out waves that will be received at any distance at which they can be picked up in the form of musical sounds instead of the ordinary crackle of the wireless. As a result of these musical indications the receiver is always able to pick out the waves of the French wireless plant from all the other storm or wireless waves with which the air may be filled. Waves can be sent out with a length of from 3,000 to 13,000 yards.

A RESEARCH TYPE OF DETECTOR.

Herc with I present drawings and specifications of a detector comprising two dis-
The How and Why of Radio Apparatus

By H. WINFIELD SECOR, Assoc. I. R. E.

NO. 9—TELEPHONE RECEIVERS.

From time to time we will describe one particular instrument used in radio, the telephone transmitting or receiving set, explaining just how it works, and why. We have received so many requests from new readers asking for explanations that we have decided to publish this matter in serial form. In the course of several issues all of the principal transmitting and receiving apparatus will be treated. For the ninth paper is TELEPHONE RECEIVERS.

The telephone receiver as applied to radio-telegraphy and telephony is one of the most sensitive electrical detecting instruments ever devised. Moreover, this does not mean that the radio receiver, as it is usually termed in wireless parlance, is the most efficient detector of weak electric currents. Quite the contrary, for it has been as a rule received for such a receiver has an over-all efficiency of only five per cent!* It was found by H. Abraham that less than one thousandth of the power is transferred from the wire to the air, is transmitted and returned to the air in the form of sound waves. Siemens conducted investigations which proved that the force of the air vibrations operating on a transmitter or microphone is ten thousand times greater than that of the vibrations representing the telephone current. Hence, of course, all must be wound with a pure insulated copper wire, and the size of wire used depends upon the resistance desired, from No. 30 B. & S. gage for a 75 ohm phone to No. 42 or smaller for a 1000 ohm or higher resistance phone.

The performance of the receiver set up or maintains a constant magnetic force acting on the iron diafragm, this action being more apparent from Fig. 1-B; thus, when the receiver has been wound down properly, the diaphragm will be held rigidly at a slight distance from the pole-pieces, and will be unaffected under normal conditions. The flux from the permanent magnet passes up one pole-piece across the air gap to the diafram, then down to the second air gap, thru the second pole-piece and thence completes the magnetic circuit. If the cap is not screwed down sufficiently tight, or if the magnets are not properly adjusted to the permanent magnet flux may be sufficient to pull down the diaphragm against the pole-pieces in which event the receiver has to be re-ruled, or the trouble may be overcome by tightening up the cap, or also in some cases it becomes necessary to place one or more paper rings under the diaphragm where it rests on the shell.

The action of the telephone or radio receiver is the same in every case. The vibration of the diaphragm so as to set up acoustic waves in the air is caused by sending a current of constantly changing strength around the coils in the telephone pole-pieces. These currents in the case of the telephone are controlled by a microphone in a well-known manner, and each current fluctuation along the circuit follows accurately the fluctuations of the voice. These current fluctuations, which often occur at a rate of several hundred per second pass thru the magnet coils in the receiver and cause constant changes in the magnetic flux acting on the diaphragm; the flux from the electro-magnet coils either strengthens or weakens the flux from the permanent magnet which acts normally on the diafram, keeping it under constant stress. Where great sensitivity is desired, it is claimed that a permanent magnet thus used to "stiffen" the diafram causes it to respond more readily to large alternating currents. It is becoming standard practise in the telephone field to make more and more use of plain ungalvanized receivers, which have been found to give in every case a perfectly satisfactory manner.

Probably the most important part of the receiver is the diafram. This is usually made of a high grade soft annealed iron which is then coated with Japan to prevent rusting, and in the best types of radio receivers the diafram is Sherardized to prevent rusting. Gold plated diaframes have also been used. The diafram of the receiver should be of sufficient size to transform the vibrations created in the magnetic field into corresponding vibrations of the air which constitute sound. The diafram itself may be of the magnetic system, incidently as part of the electric system, and finally as a mechanical vibrating system. In each of these relations, electrical, mechanical and acoustical, the original sound or signal requires that the motion of the diafram shall correspond in respect to the frequencies of the original sound of one, two or three octaves, etc. For radio receiver circuits where the current is usually of the order of a few milliamperes, and the voltage but relatively small, only a volt, it has been found that several parts of the receiver need redesigning and will bear a number of changes in proportion that would not augur well for the receiver designer if he attempted to work on a standard telephone circuit, where plenty of current and voltage are available. Experience in radio receiver design has shown that the diafram should be slightly less than two inches in diameter and clamped firmly all around the edge, the diafram itself being from four and eight mils thick. The natural pitch or vibration period of the diafram will be higher as the diameter and the thickness decrease. Of course, when designing the pole-pieces should be so near to the diafram as almost to pull it against them, for to this reason the magnetic pole-pieces should be adjustable, as it will be found in practice that temperature has considerable to do with the best operation of the receiver, the diafram itself reacting considerably under changes of temperature, which may easily range from several degrees below zero in northern climates up to one or fifteen degrees Fahrenheit in the Tropics.

The technical consideration of the action taking place in a radio or telephone receiver is best understood perhaps by analyzing the changes occurring in the magnetic circuit, which is of course the all-important factor involved in the transformation of electric currents into sound waves. The pull on the diafram is approximately proportional to $\phi$, where $\phi$ is the magnetic flux passing from pole to pole thru the metal of the diafram. A current in the windings makes the pull ($\phi + d\phi$). The increased pull due to the current is proportional to $2\phi + d\phi$, neglecting a relatively small quantity. Therefore, the greater the permanent flux, the greater the efficiency of a given instrument is increased by strengthening the magnets or by using thicker diaframes, also by reducing the air gaps between the diafram and pole-pieces, but magnetic diafram itself sets the limit to useful increase of strength of magnet, as readily becomes evident. If, with a certain thickness of diafram we understand the maximum strength of the magnet in the receiver, the superfluous magnetic flux which cannot be

Making a Six-Foot Piano Lamp

THE piano lamp here described may, of course, be constructed to suit the fancy of the individual as to finish and design. The finish desired will alter the kind of wood to be obtained. For a mahogany finish either birch or whitewood may be used as substitute for genuine mahogany. I used whitewood and the result was entirely satisfactory, both as to the finish it took and the ease with which it was worked. In the following explanation I will describe the lamp as I built it, but as aforesaid the design may be altered without difficulty.

WOODWORK DETAILS.

Material—Two pieces 2"x4"x3'x6". One piece 12" square by 3" thick.

Plane one 4" side of each 2"x4". Running lengthwise thru the center of each of the plane sides cut a groove 3/4" wide and 3/4" deep. These grooves extend to within two inches of each end (Fig. 1). (Grooves may best be made with a dado saw.)

Now glue the pieces together, planed sides next to each other. You now have a piece 4"x4"x3'6" with a hole 3/4" square extending thru the center to within two inches of each end. (When gluing be careful that no glue laps over into the center hole.)

When the glue is thoroughly dry the piece is ready for turning. The two inches of solid wood at each end affords a grip for the head and tail pieces of the lathe. Fig. 2 shows the piece ready for turning and the dotted lines shown at it will be when it is turned up. (Observe dimensions carefully.)

After it is turned and smoothed with fine sandpaper, remove from the lathe and cut off at A and B (Fig. 2). It will then re-

semble the dotted lines in Fig. 2 and the hole will extend completely thru the post. Now cut off one-half inch from AF (Fig. 2).

For the base take the 12"x12" piece and cut out a circular piece with as large a diameter as possible. Screw this onto a face-plate and insert in a lathe for turning. Fig. 3 shows the pattern. A hole 3/4" in diameter is bored thru the center of the piece. Another hole (A-Fig. 3) 1/2" in diameter is bored from the edge of the base to the inside hole and parallel to the bottom.

We will now leave the woodwork and turn our attention to the electrical details.

ELECTRICAL DETAILS.

Material—1 brass piece A-Fig. 4; 1 brass nipple to fit threads in the bottom of the brass piece (B-Fig. 4); 1 brass flange to fit the nipple (C-Fig. 4); 1 attachment plug; 3 brass pull-chain sockets (D & D Fig. 4); 11 feet of silk covered two-wire lamp cord.

The brass piece (A-Fig. 4) is made especially for the purpose. I found it at a hardware store that deals largely in lamps. It consists of a heavy brass tube tapped at the lower end and fitted at the upper with a piece as shown in the figure, from which two nipples extend to screw the sockets onto. This upper part is hollow to provide a place to make connections. Up thru the center of the cup thus formed and extending some distance above the top, is a rod threaded at the upper end and fitted with a nut. The cup is also provided with a cap with a hole in the center to pass the upright rod.

I took the above piece to an electrical supply house and had the nipple and flange fitted to the bottom.

The plug is either a crew plug or one that has two prongs which fit into slots in the socket.

The chains on the sockets will probably be too long. To remedy this screw both sockets onto the nipples on the post and set the post on top of the wooden post. You will then see how much too long the chains are and how many beads it will be necessary to take off. Now remove the sockets and disassemble each. Take the inside part and you will observe that the chain runs thru a short tube and over a small drum. At the end of the drum the end bead of the chain fits into a slot. Remove the chain from the slot and take off as many beads as you wish. When this is done put what is now the end link of the chain into the slot and reassemble the socket.

The cord may be obtained in brown, red, or green. A color should be chosen that will look well with the shade you select.

ASSEMBLING.

Pass one end of the twin conductor lamp cord thru hole A in foot (Fig. 3), and up thru the large one. Then pass it up thru the hole in the vertical column. Now cut off about six inches of the end of the cord, remove the outside silk covering and the cotton covering of each wire leaving two six-inch rubber covered wires. Take one of the sockets apart and screw the top part onto one of the nipples on piece A (Fig. 4) and lock it with the set screw provided. Remove the rubber from each end of each of the six inch wires. Pass an end of each wire thru the nipple and top of the socket.

(Continued on page 210)
THE power is not given to all persons, or for that matter to any person, to look into the future and see what is in store for them. Still quite a lot of amusement may be obtained from the electrical instru-

trations. At Fig. 1 is shown a side view of the device. At A is a small battery motor mounted on a shelf. The cardboard or tin disk is shown at B, and is mounted on the motor shaft by means of a good disk C, which may be cut from a small spool.

The window H allows the answers on the disk to be viewed. The window may be of any convenient size and covered with glass if desired. After determining the width of the window, the face of the disk should be divided up in a number of parts of the same width.

Inside these divisions the "answers" are written or printed by means of a pen. The edge of the disk is nicked between each answer and a light spring attached to the front of the box bears against the edge of the disk and dropping into the notches will stop the disk with a reply directly under the window.

The microphone on the front may be a regular telephone transmitter. The relay can be easily made by following the details shown in Fig. 2. The magnet may be taken from a high-resistance polarized ringer, the armature is a strip of brass bent into a loop at one end and placed over the support G, bent as shown. An iron piece is riveted on opposite the magnet. The contact F is supported by a brass standard and makes contact with the brass strip when the magnet attracts it.

The complete wiring diagram is illustrated at Fig. 5. The switch S, serves to open the two circuits when the apparatus is not in use. The posts are provided for connection to the battery, and these are shunted across the "break" of the relay and in addition to adding to the mystery of the device, will at times give the person holding them a slight shock, due to the reactance of the motor. They likewise reduce sparking at the contacts.

To use the oracle, close switch S and grasp the handles. Holding the mouth about two inches from the mouth piece of the transmitter, speak clearly and distinctly into the transmitter. The disk will start to spin and stoppage, will give the answer to the question asked. The replies may consist of any words, for instance, "Certainly," "Yes," "No," "How Foolish," "Of Course Not," "Without a Doubt," "Act Sensible," etc.

A RELIABLE WEATHER GLASS

A test tube about 10 inches long and ½ inch in diameter is fastened to a base or hung up by a wire. In this test tube are put: 248 grains of gypsum, ½ gram of potassium chromate, 2 ounces of pure alcohol, 2 ounces of water. If the ingredients do not mix easily, the tube should be put in warm water or shaken thoroly. After a cork is put in the tube, it is ready for work.

Following the weather, which the changes in the liquid denote:
- Clear liquid—Bright weather.
- Crystals at bottom—Thick air, frost in winter.
- Dim liquid—Rain.
- Dim liquid with small stars—Thunderstorms.
- Large flakes—Heavy air, overcast sky; snow in winter.
- Threads in upper part—Wi dy weather.
- Small dots—Damp weather, fog.

Rising flakes which remain high—Wind in upper air.

Small stars in winter on bright, clear, sunny days—Snow in a day or two.

GEORGE EDWIN SPITZMILLER.

INVESTIGATION OF INDUCTANCE COILS.

Extensive research on the inductance and resistance of standard coils at different frequencies has been carried out at the Bureau of Standards. A careful study has been made of the factors which cause the inductance of a coil to decrease and the resistance to increase with increasing frequency of current. The most important of these are (1) electrostatic capacity between the windings, (2) energy loss in the insulating material caused by dielectric hysteresis, (3) skin effect in the conductors, and (4) eddy currents in neighboring masses of metal. The effect of all of these can be reduced by proper design.

A large number of coils have been constructed and measurements made to determine the change of resistance and inductance with frequency. Methods have been devised for determining the effect of each of the factors enumerated above on these coils. The experimental determination of the skin effect has been found most difficult. In order to check the experimental values on skin effect theoretical formulas are needed. At present the only satis-

factory formulas are those which apply to a straight wire. By means of a new method other formulas are being developed.
A Reversing Switch for Small Motors

By ALLEN Q. SJOHOLM

No doubt many of the readers of this magazine are owners and operators of small low-voltage motors. Some of these motors have already been provided with reversing switches by the manufacturer, but the majority are not so well off. I present, herewith, details for the construction of such a switch.

This switch is of convenient size; it is simple in construction and operation; it may be mounted on a switchboard or it may be used wherever the motor is located. The wooden pieces of this instrument are all of ½-inch oak or any such hard wood. They should be well planed and sanded if you wish a neat-appearing instrument.

The base or back is four inches square. All the edges have a ¼-inch chamfer. A larger one will not look well. Holes may be drilled near the edge so that the instrument may be fastened to the switchboard if so desired.

The top of the box that fits on the base is 2½ inches by 1¼ inches. It has a groove, cut lengthwise thru the middle, ½ inch wide, ¾ inch deep, continuing the whole length of the top. On the base side of the groove are four holes to receive binding posts. The bottom is exactly the same as the top, except in that it has no holes for binding posts. The sides are 3 inches by 1½ inches; they are without grooves. For reasons that will be explained later, they are fastened to the other parts by screws, not nails.

The front piece is 3 inches square. In the center is a hole large enough for the shaft to turn in easily. The location of the points “forward,” “off” and “reverse” may be found in the drawings.

The inner base is 2½ inches by 2½ inches. It must be made thin enough to fit in the grooves in the top and bottom. Like the front piece, it has a hole of the same size in the center. Located on a circle ½ inches in diameter are four holes to receive switch points. These holes are placed so as to form a square whose sides are parallel to the sides of the box.

The movable part is of fiber ½ inch thick. On the side facing the inner base are fastened two circular pieces of sheet brass or copper as indicated. The lengthwise center of these strips must lie on a circle, ½ inch in diameter (see drawing). They must be in the form of an arc of a circle, 1½ inches in diameter. They should be at least ½ inch wide. Their ends must be at any rate ½ inch apart and not more than ¾ inch apart (see drawing).

The shaft or shank can be made from a nail; about an eight-penny. It is first cut to the required length. The shaft passes thru the hole in the center of the inner base; thru the movable part, and thru the front piece. To make it work more easily, a washer is placed between the head of the nail and the inner base. A washer placed between the pointer and the front piece would work to good advantage. The shaft is securely fastened to the movable piece, the pointer, and the knob. However, it must turn freely in the hole in the inner base and the front piece. The knob on the end of the shaft should be a typewriter knob, preferably. This type of knob can be fastened to the shaft more securely than any other kind. Also it can be removed more easily.

It will not be hard for the constructor to assemble this instrument, but he must observe at least two things: First, he must see that the brass strips are in good contact with the switch points, and, second, that the indicator and movable piece agree. The reason for fastening the sides by screws is this: If something should go wrong inside the box, the sides need to be removed in order to get at it.

The various positions of the movable piece according to the indicator are found in the drawings. All connections can be made more easily from the drawings, so I will omit them here.

The constructor can stain or paint his instrument any color that he may desire. If he does not, it should at least receive a coat of shellac.

It is a very good plan for the constructor to paste or cut the numbers of the binding posts on the top. These numbers will be found in the drawings. To save time and trouble, a diagram of the connections from the switch to the motor should be fastened to some convenient place on the instrument. This diagram will also be found in the drawings.

This design of switch lends itself to many other problems besides that of reversing motors. It can be used effectively in three-way lamp control systems in conjunction with the usual type of three-way switches. It serves as a four-way switch.

Wiring Diagrams and Successive Positions of Movable Blades of Motor Reversing Switch. This Switch Can Also Be Utilized as a "Four-Way" Switch in Composite, Three-Way Light Control Systems.
ELECTRICAL EXPERIMENTER

A HOME-MADE READING LAMP.
When drawing or reading, a good light is often necessary nearby. A reading lamp may be easily made from some old gas piping and odd parts, which tho not quite ornamental enough to adorn your library, will serve very well when you are “burning the midnight juice” in your den, trying to solve “trig” problems. The base of the lamp is made of a rather heavy paper weight which has a few ornamental beads turned on it for appearance. On the top of this an old switch base is fastened with two machine screws, which thread into holes in the paper weight tapt for that purpose. The weight should be at least 4" in diameter.

CAT SHOCKER.
Many a night when you were just about going into the land of dreams you were prevented from further enjoyment by musical echoes in your back yard academy. I have devised a way to stop “Tom” from making his nightly debut on your back yard fence, and it will now be up to him to hire another hall. Most amateurs are not using their coils at present and are at a loss to know what to do with them. I will tell you. Cut up several pieces of tin 2" x 3", 12 or 14 will do, and nail them along the top of your fence, separating them about 8 or 10 inches. Now run two well insulated wires along the side of the fence. These should be connected to the secondary terminals of the spark coil. Connect them as described in diagram and you won’t be bothered with any more feline opera concerts. When “Tom” gets his two front feet on one strip and his back feet on the other, press your key and "Tom" will see stars.

Contributed by FRANCIS ZIESSE.

Do You Own a Spark Coil? If So, Then "Cat Concerts" on the Back-Yard Fence at Midnight Are Soon Brought to a Grand Finale. Hook Up the Coil With Some Tin Plates Scattered Along the Fence. The Spark Coil Will Do the Rest.

AUTHORS!!!
All matter intended for publication—not only by us, but by any other magazine or newspaper as well—should be written on one side of the paper only and in ink. If it isn’t, somebody else must copy part of it off on another sheet before it is given to the printer.
An Electric Hour-Striking Mechanism

By THOMAS REED

A earnest "Bug," who had evidently just completed an electric clock according to specifications, wrote me asking how to make a striking-mechanism to go with it.

To describe its perfections, and by that time it was three o'clock.

"Now," said he, "it's going to strike." It did; Ye Gods, it did. It struck the three, and then went on to get all its striking done up for the day. The inventor, his face a beautiful pink, thumped on the case to remind the mechanism of its duty, but no it was doing. At the twenty-seventh stroke, his endurance gave way, and he stopt by poking a finger in the works.

It was a dirty trick for baby to play, just when papa's $50,000 depended on his speaking his piece right. Sometimes clocks are almost human.

Well now, to return to that "Bug," his letter seemed to bring a sort of inspiration with it; and after telling him dolefully to save the problem, with perpetual motion, to think over at night as a cure for insomnia, an answer to it happened along just as casually and naturally as a fellow doing in to cut off your gas meter for arrears. So as the "Bug" (whose name was Walter Fran- seen) furnished the inspiration, he is hereby declared joint inventor of the apparatus, which is shown in Fig. 1.

To begin with, while this mechanism could be incorporated in all time-wairs, it's better to drop it down below, and connect it with the hour-hand arbor by chain-wheels, or even pulleys and a rubber band, as there is almost no power to be transmitted. In that way, you can have the pleasure of seeing it go; and if it cuts up any shines, as Walter has, you can get at it handily with a half brick or a hammer.

As the picture is drawn, the clock is just ready to strike one. The cam A, attached to the minute-hand arbor of the clock, and moving in the direction indicated, is arranged to drop the flat spring D, which rests on the cam at D'.

When the spring does drop, the point on it where the D raises strikes on the contact point C and completes the electrical circuit. Follow it around. It first enters the little forked trigger CC. The bent top of this trigger forms a contact with the flat spring KK at the point JJ. On the circuit, thru the battery BB, support AA, spring LL, across to contact Q at point RR, thru the magnet L, and back to C, where we began.

Now, what happens? The magnet L, of course, is energized by dropping itself the armature K attached to the lever I, pivoted at J, which carries the heavy hammer EE by its stem HH. Righto! But also attached to the lever I is the stud N, carrying the pawl M. As this pawl is pushed to the right, it pushes along the circular rack S, till just as the hammer strikes the gong, it has pushed it to the extent of exactly one tooth; and the click O is holding that gain of one tooth, and will hold it till we get ready to make it let go.

Now, having struck our one o'clock on the gong, we want to stop things. Up above, in the clock-works, of course the contact D, C, is still closed; it would be separated for 10 or 15 minutes yet, as the cam A goes around with the minute-hand. But look at our excellent nubbin S', protruding like a borer thumb from the end of the rack S. The nubbin has now reached the spring LL, pushed against it, and separated the contacts Q and R. The magnet L is "killed," the armature-lever I is drawn back to the stop V by the spring F, and our mechanism goes to sleep till it's time to make preparations for striking "two."

Next, we introduce the volute-shaped piece W, well known in the clock-making art as a "snail." This snail is constantly moving in the direction of the arrow, at the same rate as the hour-hand of the clock above. Attached to the same arbor, and moving similarly, is the wheel X, with two Projecting-pins, X, X.

Fifteen or twenty minutes after we have so brilliantly struck "one," the pin X' strikes the end of the forked lever I, pivoted at U; and X', continuing further, raises T. The top fork of T, which is naturally raised also, carries the two pins T' and T, which bear on both the click O and the pawl M.

We left Mr. Click here,But he shut the rack S, and resolved to continue holding it or know the reason why. Well, the reason is here. On a little further raising of T, the click is lifted out of the tooth, and the rack S falls till the pin S' hits somewhere on the edge of the snail. The small, however, has been moving to the right, and the pin falls at the point W, where the diameter has lessened by just the amount of one rack-tooth. Two teeth in all, then, are ready for our next hour-strike.

A few minutes more, and the pin X" drops the lever T, and the latter "passes the brush," by dropping the click and pawl into the rack, ready for operation. It must be remembered that when the rack S fell, it released the spring LL, and closed the contact Q, R', but long before this, the contact D, C, back in the clock was opened, so we don't start yet. But we are all set again, and the instant DC is closed, the striking-operation is repeated; only now the rack S has two teeth to go before the

ELECTRICAL LABORATORY

Contest

(Special Prize $5.00)

Experimental Laboratory of John E. Woodrow

The accompanying photographs illustrate one of the most interesting, real dyed-in-the-wool Experimental Laboratories that we have ever had the pleasure of publishing, Mr. Woodrow has recently joined the U. S. Navy like many other illustrous young men thruout the country, who feel that they can do the utmost good for their government by offering their skill and talents to Uncle Sam. This youthful electrical and radio genius calls as his home town, Peoria, Illinois. Mr. Woodrow's laboratory, as the reader will quickly perceive, is not conspicuous by its size or other luxurious appointments so often associated in the minds of embryo engineers with such workshops, but what

he really has accumulated in his laboratory is a very complete assortment of tools and various rinktums, including miscellaneous parts of electrical apparatus so dear to the heart of every "Bug." One of the photographs shows the work bench which is provided with a small lathe driven by an electric motor, the bench also being provided with large and small hand vises, and so forth. The tool equipment includes screw drivers and files of all sizes, hack saws, wrenches, hammers, chisels, pliers, brushes, stocks and dies, wire, boxes containing a generous assortment of beloved "junk," machines and wood screws, nuts, washers, etc.

Among the other "high lights" in Mr. Woodrow's excellently equipt laboratory, we find an electric fan, storage batteries, a complete wireless receiving set and various parts of both large and small radio sets, primaries and secondaries for a large Tesla coil, electro-magnets and solenoids, small motors, parts of a Cooper-Hewitt mercury arc rectifier, as well as parts of a motion picture projector.

One part of the laboratory is devoted to "Experimental Chemistry" and contains a large assortment of the various chemicals needed by the experimenter in this branch of science, and as may be seen, the owner of this laboratory keeps his chemicals in well-stopped bottles and tight-fitting tin cans.

In connection with the chemical and electro-chemical experiments as well as in researches in the field of fluoroscopy, there is provided a considerable assortment of electrical apparatus, including various measuring instruments, such as ammeters and volt-meters, batteries both wet and dry type, motor generators, rheostats of various sizes, galvanometers, X-ray tubes and other special vacuum tubes, small weighing balances, and among several hundred other things, the inevitable supply of father's cigar boxes suitably decorated with highly colored lithographs of the Queen of Sheba, or some other equally famous or possibly infamous celebrity, situated in the social scale as remote as possible from the scientific and idealistic "high-brows" of budding scientists. However, these cigar boxes are possible means of obtaining "brick dust," suited for the various experimental purposes. Mr. Woodrow has started collecting cigar boxes, which are in abundance in this community, and he is doing it with the idea of making them into concrete or other building materials.

Edisons and Teslas, which fact for some reason we have never been able to fathom. Why doesn't some enterprising cigar manufacturer awake to the fact that there are several hundred thousand live, wide awake electrical and radio "Bugs" in the United States alone, who would boost the sale of any cigar no matter how close its relation might be to the well-known "piece of rope," so long as little Johnny or Thomas can influence his Dad to buy that particular smoke, for the very good reason that he wanted one more cigar box to complete his nest of drawers, each of them decorated with the likeness of some great electrical or scientific personage. Just think of it, "Bugs," what a glorious universe this would be, if the powers that reign in the tobacco world, would only take up this suggestion and make it possible for us to obtain a more or less complete collection of the invaluable cigar boxes decorated with the "physog's" of Messrs. Tesla, Edison, Steinmetz and Thompson.

Here's a Regular Experimental Laboratory and It Was All Built Up By an Amateur—Mr. John E. Woodrow, of Peoria, Ill. Note the Complete Assortment of Tools, Chemicals and Electrical Apparatus:

An Inexpensive and Thorough Way of Learning Radio Codes.

By F. V. Campbell.

The following method of learning wireless codes, without the use of teacher, other than ordinary phonograph, is as follows: In case of an Edison or other cylinder record phonograph, the student can either have a record made by a friend who is competent, or get someone to make it for him, and on reproducing the same, it will give almost an exact tone of a regular commercial wireless station, provided the record has been properly made. A disc record would necessarily have to be made at the factory, as no means are supplied whereby a person can make their own records on the discs. A phonograph is set up, with a blank record on, directed properly, and the code is then made, first, by the maker pronouncing the letter, then making it in wireless code characters, using, instead of a regular sending set, the second "C" above middle "C" on the organ, which gives approximately the same tone as a standard commercial wireless sending station. Then by voices groups or letters, first pronouncing the word, then making it in the code.

The method has been tried out by the writer in learning the Continental code, and has given the most complete satisfaction. The use of the organ in making the record gives a sustained tone pitch, which is essential to wireless receiving, and sounds almost exactly like a commercial station sending. If properly made on a wax cylinder, it will continue to give clear readable signals long after the student has mastered the alphabet from it. A great many persons would like to learn the code who have practically no one to send to them, without which they are at a great disadvantage, but who do possess a phonograph, and at very small expense could either make a record or secure one from someone who is equip to make them.

Don't miss the article on "Harmonics—Part II"—by Prof. F. E. Austin, in the August issue of the "Electrical Experimenter." It explains the analysis of irregular shaped alternating curves.
This department will award the following monthly prizes: First Prize, $3.00; Second Prize, $2.00; Third Prize, $1.00.

The purpose of this department is to stimulate experimenters towards accomplishing new things with old apparatus or old material, and for the most useful, practical and original idea submitted to the Editors of this department, a monthly series of prizes will be awarded. For the best idea submitted a prize of $3.00 is awarded; for the second best idea a $2.00 prize, and for the third best prize of $1.00. The article need not be very elaborate, and rough sketches are sufficient. We will make the mechanical drawings. Use only one side of sheet. Make sketches on separate sheets.

**FIRST PRIZE, $3.00**

**A NOVEL ALCOHOL LAMP.**

Procure six or eight inches of platinum wire, about the hundredth part of an inch in thickness; coil it round a small cylinder ten or twelve times, then drop it on the flame of a spirit lamp, so that part may touch the wick and part remain above it. Light the lamp, and when it has burned a minute or two put it out; the wire will then be ignited, and continue so long as any spirit remains in the lamp.

Lamps manufactured on this principle are sold by some of the chemists in New York and London.

A liquid produced from two solids: Mix equal portions of sulfate of soda and acetate of lead, both in fine powder; let them be well rubbed together in a mortar, when the two solids will operate upon each other, and a fluid will be produced.

A solid produced from two liquids: If a saturated solution of muriate of lime be mixed with a solution of carbonate of potash (both transparent liquids) the result is the formation of an opaque and almost solid mass. If a little nitric acid be added to the product, the solid mass will be changed to a transparent fluid.

Contributed by **Eliott Rabe.**

**GLASS INSTRUMENT FEET.**

It frequently happens that the amateur electrician wants good insulating feet for other. The size of wire given is for 110 volt A. C. circuits. I have used this scheme and found it very satisfactory.

Contributed by **Emil Capelle.**

**CONSTRUCTION OF NOVEL MAGNETIC RECTIFIER.**

The drawing submitted herewith shows the construction of a magnetic rectifier that uses the whole cycle of the A. C. current all the time, which results in a current almost as steady as from a storage battery. The rectifier is made as follows: The coils are both wound in the same direction. Wire required, 1,500 feet, No. 30 S. S. C. wound on each core. The cores measure 2 inches long by 3/16 inches diameter and are preferably made of soft iron wires.

Two bar magnets are pivoted in the center and placed as close as possible to the cores without touching them. One side of A. C. line is grounded on one core, the other side of line to the other core. The D. C. is taken from each pivot that holds permanent magnets. The permanent magnets should have poles facing each other.

**SECOND PRIZE, $2.00**

**OLD "SHOE NAILS" MAKE GOOD SHAFTS.**

Of course a "bug" can use old "shoe nails." I have used them myself as the "makings" of a laminated iron core for a small induction coil, together with some 3/4" brads. This sketch shows how the wax was used to hold them in. The nails may be annealed by heating to a dull red and then allowed to cool slowly before placing in the tube.

Contributed by **Harry W. Dryden, Jr.**

**A MOTOR-DRIVEN SCREW DRIVER SAVES TIME.**

A handy and practical screw driver, operated by a motor, will more than pay for itself in a short time. An electric motor is fastened at the left side of a base of wood. A small wooden structure at the right side is built of posts and a small hole is drilled at the top, to admit and allow the free movement of the steel shaft with the chuck. An arrangement by which the motor rotates the steel shaft (with chuck) is clearly shown. This device consists of two miter gears on one end of motor shaft and the other on the chuck shaft. A chuck is threaded on the upright shaft, and with a set of bits, drills, taps, etc., very good and quick work can be done with this apparatus.

**THIRD PRIZE, $1.00**

**Here's a Simple Form of a C. Rectifier That Will Appeal to Amateur Electricians.**

Drill Tap.

Drive Your Machine and Wood Screws By Motor.
Much has been written about the guns used in the present European War and it is not out of place to dig down to the root of the whole thing and find out what is the real source of the explosion in the gun chamber. Most guns are set off by means of a priming cap and the substance used inside the priming cap is the subject of this article.

Mercuric fulminate is the active substance in the priming cap. This substance is prepared by the action of alcohol on a solution of mercury dissolved in an excess of nitric acid; and as this action is of a violent character, some care is necessary in order to avoid an explosion. On a small scale, the fulminate may be obtained without any risk by strictly attending to the following directions:

Weigh out, in a watch-glass, 25 grains of mercury, transfer it to a half-pint beaker, add half an ounce (measured) of ordinary concentrated nitric acid (sp. gr. 1.42), and apply a gentle heat. As soon as the last particle of mercury is dissolved, place the beaker upon the table, away from any flame, and pour into it, pretty quickly, at arm's length, 5 measured drachms of alcohol (sp. gr. 0.87). Very brisk action will ensue, and the solution will become turbid from the separation of crystals of the fulminate, at the same time evolving very dense white clouds, which have an agreeable odor, due to the presence of nitrous ether, ethyl hydrate and other products of the action of nitric acid upon alcohol. The heavy character of these clouds is caused by the presence of mercury, tho in what form has not been ascertained; much nitrous oxide and hydrocyanic acid are evolved at the same time.

When the action has subsided, the beaker may be filled with water, the fulminate allowed to settle, and the acid liquid poured off. The fulminate is then collected on a filter, washed with water as long as the washings taste acid, and dried by exposure to air.

On a large industrial scale, the preparation of mercuric fulminate is carried out in the open air, under sheds. At Montreal, 300 grammes of mercury are dissolved in 3 kilogrammes of colourless nitric acid of sp. gr. 1.4, in the cold. The solution is transferred to a retort, and 2 litres of strong alcohol are added. In the summer no heat is applied, and the vapors are condensed in a receiver and added to a fresh charge. When the action has ceased the contents of the retort are poured into a shallow pan, and when cold, the fulminate is collected in a conical earthen vessel partially plugged at the narrow end. It is washed with rainwater and alcohol, and it usually takes 20% of water, being stored in that state.

Mercuric fulminate is represented by the formula HgC\(\text{NO}_3\), being derived from the hypothetical fulminate Hg\(\text{CN}_2\text{O}_4\) by the substitution of Hg\(\text{CN}_3\text{O}_4\) for H\(\text{CN}_3\text{O}_4\). Its production by the action of nitric acid upon mercury and alcohol may be explained by the following reactions:

1. Mercury, dissolved in nitric acid, yields mercuric nitrat and nitrous acid.
2. Nitrous acid, acting upon alcohol (ethyl hydrate), gives nitrous ether (ethyl nitrat) and water.
3. Ethyl nitrat, acted on by another molecule of nitrous acid, gives fulminic acid and water.
4. (Continued on page 197)
Experimental Chemistry

By ALBERT W. WILSDON
Twenty-Sixth Lesson

CARBON DIOXID.

Experiment No. 133.
Preparation from Calcium Carbonate and Hydrochloric Acid.

HAVE (1) a splint; (2) 10 cc. of limewater in a test tube; (3) 10 cc. of blue litmus solution in another tube; (4) 10 cc. of barium hydroxid in a third tube. These should be ready to apply the several tests while the experiment is under way.

Either an Erlenmeyer flask of about 250 cc. or a wide-mouth bottle may be employed for the generator (see Fig. 121). Arrange the thistle and delivery tubes in the two-hole rubber stopper as shown, carrying the delivery tube at right angles into the receiving bottle. Put into the generator 20 or 25 grams of marble chips (CaCO₃) and cover with water, which serves to dilute the acid, which is next poured in thru the thistle tube, a little at a time, but enough to insure good action. First collect some of the gas by downward displacement in a wide-mouthed bottle that may be left open. When action is well under way, light the splint, and thrust it into the receiving bottle. Repeat these several times, and determine whether or not it is combustible or non-combustible; or a supporter or non-supporter of combustion.

The equation taking place in the generator is:

1. \( \text{CaCO}_3 + 2\text{HCl} \rightarrow \text{CaCl}_2 + \text{H}_2\text{CO}_3 \)
2. \( \text{H}_2\text{CO}_3 \rightarrow \text{H}_2\text{O} + \text{CO}_2 \)

Now place the delivery tube in the blue litmus solution and permit the gas to bubble thru it. What action do you notice? Further try its solubility by passing some into plain water and then testing the water with litmus paper. From these tests, does it suggest that the gas combines with the water or not? The gas may also be tested by trying to collect some over water and noting the rapidity with which it goes thru the water.

Allow the gas to bubble thru the prepared limewater (calcium hydroxid) and note the familiar effect. Permit the bubbling to continue. The precipitate should gradually dissolve. What could cause this paradoxical result? After the time in this water solution is all combined and precipitated, what would become of the surplus carbon dioxid? Knowing that most acids act on carbonates and dissolve them, if the product of that action is a soluble substance, can you explain the disappearance to use over 10 grams of the carbonate, which is then covered with water and the acid poured in in small successive amounts, the delivery tube going over into the solution to be used as a test. Employ the limewater, the barium hydroxid, litmus, and combustion tests. In this manner try the action of nitric acid and on calcium carbonate; also try sulfuric acid, separately on calcium carbonate. Make full notes of each, including tests and equations.

Next let what you consider carbonat in each of three tubes and act on it with the three acids (each in a different tube) hydrochloric, nitric and sulfuric, making full notes as you go.

Use potassium carbonate with the same acids in like manner.

What general conclusion can you draw concerning the method of preparing carbon...
"Electrical Laboratory" Contest

In this issue we publish an interesting story with excellent photos, describing one Amateur Electrician's experimental laboratory. Now "Bugs"—we want to publish a similar article each month. Here's our proposition: Why not write up your "Electrical Lab." in not more than 500 words. Dress it up with several good, clear photographs. If we think it good enough we will publish the article in display style and pay you well for it. The remuneration for such articles will range from $5.00 to $10.00. And "Bugs"—don't forget to make your article interesting. Don't write—"I have a voltmeter, an ammeter, a switchboard," etc., ad infinitum. For the love of Pete put some punch in it! Tell us what you do with your instruments and apparatus. You don't mean to tell us that every Experimenter does exactly the same thing. "We" know different—but from the general run of such articles which we have received in the past, one would naturally think every "Lab." exactly alike. Remember—send a photo of YOURSELF along. Typewritten articles preferred.

A GROUP OF REPRESENTATIVE AMERICAN AMATEUR LABORATORIES.
Animated Shadowgraphs

(1,263,355; issued to Pierre Ar-tigue.)

An improved method of producing animated shadowgraphs which involves the use of a powerful electric lamp suitably positioned after the manner illustrated. The screen on which the shadowgraphs are produced had, preferably, painted or otherwise produced thereon a suitable background of trees, buildings or other inanimate bodies. As the moving bodies are in silhouette, they conceal the underlying portions of the background, so that these portions will not show thru the solid block of the silhouette as it is projected on the screen.

Adjustable Telephone Bell

(1,260,549; issued to William Kline.)

This patent covers a clever arrangement whereby it becomes possible for anyone to readily adjust the strength of the sound given off by the bells. The patent also describes a novel spiral spring goin, a pair of which can be made adjusting in a similar manner to that described for ordinary bell goings. For the gongs here illustrated, there is provided a pair of sound dampers, or modulators, consisting of small thin pieces of fiber, felt, celluloid, or other suitable material, which are securely fastened to the outer edge of the bells.

Electric Vibrator

(1,259,396; issued to Albert E. Hartwell.)

A type vibrator is extremely simple and consists of an insulated coil with a laminated iron armature core passing thru it, and having an arm pivoted so as to be vibrated by the alternate energizing and deenergizing of the circuit, and finally said arm having attached to it the massage implement. A spiral spring is secured within the case to act against the pivoted lever arm, so that when the coil is deenergized, this spring will force the arm hardward and withdraw the opposite end of the bar from the core.

Non-Twisting Weight for Telephone Cords

(1,259,597; issued to John A. Breen.)

This patent deals with the problem of providing a satisfactory and at the same time cheap form of non-twisting weight for attachment to the flexible cord used on all desk phone sets, so as to take up the slack in the cord, and at the same time prevent the cord from twisting. A fault which these cords are un válido.

the

produced

rangement

(1,260,549; issued to Napéleon Berg-

eron.)

As near as the reviewer can glean from the information given in the patent, the inventor sets out to solve the eternal riddle of perpetual motion. There is provided to start with, an electric boiler, the steam from which causes the steam engine to operate; this engine in turn is belted to a dynamo. The current from the dynamo can be switched on to an electric motor connected with a pump for blowing fresh cold water to the boiler, this water being pre-heated by means of the exhaust steam coming from the steam engines shown. Thus the electric circuits and steam generating apparatus work hand in hand apparently, without any energy from an outside source of electric power being supplied to the electric boiler circuits, except from a small dynamo at "starting." The

High Tension Rectifier

(1,259,149; issued to William Walk-

er Strong and Arthur Fleming Ne-

bit.)

In this rectifier the rotating commutator element is driven by a synchronous motor, and the current rectifier segments and brushes are mounted in a gas-tight chamber, so that the chamber may be filled with compressed air or suitable gases under the proper pressure. In order to maintain a suitable gas pressure the

Flapping Fan

(1,261,753; issued to August An-

dersen.)

This patent covers a unique form of oscillating electric fan or one in which the blade is made to flap up and down or sidewise as desired, by an ingenious arrangement of an electric motor supported within the commutator chamber, there is provided a small pump.
Phoney Patents

Under this heading are published electrical or mechanical ideas which our clever inventors, for reasons best known to themselves, have as yet not patented. We furthermore call attention to our celebrated Phoney Patent Office for the relief of all suffering daffy inventors in this country as well as for the entire universe.

We are revolutionizing the Patent business and OFFER YOU THREE DOLLARS ($3.00) FOR THE BEST PATENT. If you take your Phoney Patent to Washington, they charge you $20.00 for the initial fee and then you haven't a smell of a Patent yet. After they have allowed the Patent, you must pay another $20.00 as a final fee. That's $40.00! WE PAY YOU $3.00 and grant you a Phoney Patent in the bargain, so you save $37.00!! When sending in your Phoney Patent application, be sure that it is as daffy as a lovesick bat. The daffier, the better. Simple sketches and short descriptions will help our staff of Phoney Patent Examiners to issue a Phoney Patent on your invention in a jiffy.

Prize Winner. ELECTRIC HOOVERIZER. At Last Mr. Hoover May Put His Mind at Rest, for with the Application of This Marvelous Automatic Electric "Hooverizer" to All Hotels and Restaurants, not to Mention Leven-steen Million Private Families Through the Land, the Worries of Saving Grub Will Be Over for All of Us. How does it work?—Simplest Thing in the World, My Boy. You See, It Works Thusly:—When the Diner, Properly Equipped with the "Hooverizing" Machine, Eats a Certain Prearranged Quantity of War Bread, Bran Muffins and Molasses Cake, the Increase in His Girth Causes Electric Contacts B to Close, Thus Passing Current (Not Current) from Battery C, Into Alarm Bell D and Motor A. The Motor Winds Up a Cable as Shown, Which Causes the Expansible Arm to Yank the Plate E, Away from the Diner, When the Walter Appears and Scraps the Remains Into His "Hooverizing" Pail. Inventor, George I. Jones, Emporia, Kansas.

ELECTRO MUTT-MOTOR. I Hereby Declare the Following Not to Be the Correct Explanation of My World-Startling Conception for the Production of "Perpetual Motion"—First We Need a Nice Tame Mutt-Genus Mexicanos Sans Hair—His Royal Nibs Being Piously Situated on the Northeast Corner of a Lamb's-Wool Cushion, All as Illustrated. Now We Start the Motor Driving the Revolving Rubber Hands; Senior de Puppo is Much Pleased, Wags His Tail and Operates the Two Air Bellows, Thus Compressing Air Into Tank. Compressed Air from Tank Drives Pneumatic Motor Connected to Dynamo; Result, "Free Electricity" as Long as the Mutt Lives. Inventor, Harry W. Haengisen, Jr., Pompton Lakes, N. J.
OPERATING MOTORS IN SERIES.

(932) Robt. Kremr, Bronx, N. Y., writes:
Q. 1. Will it harm a small 110-volt D. C.
motor to connect in series with a large 110-
volt D. C. motor?

A. 1. Relative to the matter of connecting
a small 110-volt D. C. motor in series with
a large 110-volt D. C. motor we can assure
you that the larger machine in such a
case will have no untoward or dangerous
effect whatever with respect to the smaller
machine. The large motor, rated in this
case at 2 H. P., will not act as a "reservoir"
of electrical energy with respect to the
small motor, and it will make practically no
difference in the operation of the little ma-
chine except that so long as it is left in se-
ries with the small motor, it will cause the
speed of the latter to be below normal,
owing to the fact that the electrical resis-
tance of the 2 H. P. will cause a drop in
the E. M. F., or voltage, reaching the small
motor.

As you will see, this is in agreement with
your statement that under these conditions
the small electric drill motor does not reach
normal speed even with the large motor
starting-box arm placed in the last position
or notch for the reason above stated,—i. e.,
due to the drop of potential caused by the
resistance of the large motor. This drop in
potential is given by the formula: Drop in
E. M. F. equals resistance times current
flowing thru it.

HAMPSON'S RADIO CONTROL
SYSTEM.

(933) W. W. G., Canton, Ohio, asks:
Q. 1. Has John Hays Hammond, Jr.,
succeeded in developing his radio controlled
torpedoes so that they are interference
proof?
A. 1. As to the success attained by Mr.
John Hays Hammond, Jr., in his radio con-
trol experiments, we do not know definite-
ly as to the exact measure of success he
has found in this direction, but from all
reports which we have come in contact
with in the past few years, it seems that
he has a fairly good selective radio control
system.

We do not see, however, why you
would not do well to follow up this line of work,
as there seems to be very good room for
improvement in many ways. From our ex-
erience in radio matters, we should say
that it will undoubtedly take some very
excellent and thorough research work indeed
to make an absolutely "interference-proof"
radio control scheme for operating tor-
pedoes and the like. There is plenty of op-
opportunity for improvement in this branch
of the art regardless of the work done by
Mr. Hays Hammond's staff of experts.

BAROMETER QUERY.

(934) Electrical Experimenter, Bridg-
ton, Mo., writes the Oracle:
Q. 1. If a barometer tube is tilted at an
angle, will this change the reading?
A. 1. A particular case is that of a
water barometer, and as in any barometer
the vertical height is the important factor.
We should say that the angle at which the
tube is tilted will have no effect on the
situation except for that of the vertical
height. In other words, the length of the
line from the level of the water in the tube
is constant, no matter at what angle the
bulb is tilted.

Take note of the fact that water cannot
be raised to any greater height than 32 to
33 feet by atmospheric pressure.

WEAK MAGNETO.

(935) P. Wolfe, Alaska, asks several
queries relative to a weak ignition magneto.
Q. 1. One of the main reasons for the
magneto giving a weak spark is that the
steel magnets are usually improperly placed.
They should be placed with their N and S
poles as shown in the accompanying dia-
gram. Furthermore, the more the number
of turns of wire on the armature, the
greater the E. M. F., and the thicker the
wire, the greater the current. Therefore it
is very important to get as many turns on
as possible to get the best results for a
constant amount of current.

The way by which the steel magnets
tend to demagnetize the steel magnets of
the magneto is that the current of the battery

ODD PHOTOS WANTED AT $1.00 EACH!!!

Now is the time to make your
Kodak pay for itself in a real prac-
tical way. We are after interesting
photographs of out-of-the-ordinary
electrical, radio and scientific sub-
jects and are willing to pay $1.00 cash
for every one we can use. Please
bear in mind that for half-tone re-
production in a magazine, a photo-
graph should be particularly sharp
and clear. Of course, if a subject
happens to interest us particularly
well, we can have the photo retouched.
For the general run of subjects, how-
ever, it does not pay to go to such
expense. Therefore please take pains
to properly focus and expose your
pictures. It often happens that a
really mediocre subject well pho-
tographed wins approval over an ex-
cellent subject poorly photographed.
And don't send us plate or film "neg-
tives"; send unmounted or mounted
"prints," preferably a light and a dark one.

As to what to photograph: Well,
that's hard for us to say. We leave
that up to you, and every reader now
has the opportunity to become a re-
porter of the latest things in the realm
of Electricity, Radio and Science.
But, please remember—it's the "odd,
novel or practical stunts" that we are
interested in. Every photo submitted
should be accompanied by a brief de-
scription of 100 to 150 words. Give
the "facts"—don't worry about the
style. We will attend to that. Enclose
stamps if photos are to be returned
and place a piece of cardboard in the
envelope with them to prevent mul-
tiplication. Look around your town
and see what you can find that's interest-
ing.

Proper placing of permanent
magnets for Magneto

How the Magnet Poles of Compound Mag-
neto Fields Should Be Lined Up.
A Matchless Book
At a Marvelous Price

It cost $28,000 to compile the contents of this book.

Our Bound Volume No. 5 contains a goldmine of electrical and scientific information. No such value has ever been offered before for so low a price. A marvelous cyclopedia of electricity. A reference book of authentic information not found in any other book in print.

Volume contains twelve numbers of the "Electrical Experimenter" magazine—May, 1917 to April, 1918, inclusive. There are 928 pages, 2,110 complete articles, 1,908 illustrations, 369 questions and answers.

Size, 12" high; 9" wide; 1½" thick.

A world of electrical information; the entire electrical Progress for one year; the greatest reference book on current "Wireless"—all at a price within reach of everybody. Mind you, the book is durably bound in attractive green linen with heavy covers. Letters stamped in gold. You will be proud to have it in your library. We have only 600 copies, therefore be sure and order to-day. Shipping weight 8 lbs. Add a sufficient amount for postage, otherwise we must ship by express.

NOTE: We also have a very limited quantity of Volume 4 (1916-1917). These books contain 992 pages, 1862 illustrations. The price is the same as for Volume 5. Positively the Greatest Electrical book bargain in the World. We ship AT ONCE. Order today to avoid delay.

EXPERIMENTAL CHEMISTRY.
(Continued from page 186)

ings of soap, not over a gram in 100 cc. of soft water, heating the latter to facilitate solution. This should be reasonably clear; if it is not, use more water.

Now prepare some bicarbonate of calcium solution by passing carbon dioxide from a generator into 20 cc. of calcium hydroxide solution till the precipitate formed is dissolved. This solution must be clear, and if necessary to make it so, should be filtered. This solution is hard water.

Take 10 cc. of this solution and add the same volume of soap solution, both of which should be clear before mixing. Shake them well together and note the effect. Is a lather formed? This is soap hard water.

Take 10 cc. of distilled or other soft water and add an equal volume of soap solution. Is a lather formed in this case or a precipitate formed?

Boil the other 10 cc. of bicarbonate of calcium solution till the calcium carbonate is precipitated; then filter, and to the clear filtrate add an equal volume of soap solution. Shake, and note whether a lather or an insoluble substance is formed. Has the water been softened? What is your method of softening this sort of hard water?

Make a solution of magnesium sulfate in water, 2 grams of the salt to 20 cc. of water. Add soap solution, volume for volume, shake together, and, as before, note result. With the remaining 10 cc. see whether boiling has the same effect on the sulfate that it did on the bicarbonate.

EXPERIMENT No. 138.
CARBON MONOXID.
Preparation from Oxalic Acid and Sulfuric Acid.

CAUTION!!! REMEMBER THAT CARBON MONOXID GAS IS A DEADLY POISON, AND GREAT CARE SHOULD BE EXERCISED IN ITS PREPARATION, AND IN EXPERIMENTS MADE WITH IT. ONE PER CENT OF IT IN AIR: WOULD BE FATAL. IT SHOULD NOT BE MADE EXCEPT AT A "HOOD" AND WITH GOOD VENTILATION.

Put into a plain, thin Erlenmeyer flask of about 250 cc. capacity, 10 grams of oxalic acid crystals and pour thru the throttle tube 20 cc. of concentrated sulfuric acid.

The delivery tube from the two-hole rubber stopper leads into an intervening bottle, which contains a strong solution of sodium hydroxide, or carbonic acid, about half filling the bottle, the delivery tube reaching nearly to the bottom (see Fig. 123). From this bottle runs a delivery tube to the tray or pneumatic trough, the carbon monoxid being collected over water like oxygen. Set the flask on a triangle with asbestos and apply gentle heat. Collect three or four receivers of the gas, having one large bottle to collect any surplus, thus avoiding contamination must be done after the heat is withdrawn. When once started the chemical action will take care of itself and the heat can be withdrawn. In any event the action should be vigorous.

Water poured thru the throttle tube will cool and hinder the action.

The oxalic acid breaks up into carbon dioxide, carbon monoxid and sulfuric acid, which is a solid, consists of H, C, and O in the exact proportion to form the carbon dioxide, the sulfuric acid, and the carbon monoxid. The last will break up the acid into these constituents, but sulfuric acid aids in the operation and also absorbs the sulfuric acid, and the two gases carbon dioxide and carbon monoxid completely intermingled. Thus the function of the sulfuric acid in this experiment is only to produce a product for which it has great affinity. Remembering the affinity which carbon dioxide has for soluble hydrations, the use of the sodium hydroxide in this experiment with the carbon dioxide, thus permitting the carbon monoxid, which is insoluble in water, to be collected in a similar manner to hydrogen, the equation of the complete reaction is:

$$\text{H}_2\text{CO}_3 = \text{CO}_2 + \text{H}_2\text{O}$$

$$\text{CO}_2 + \text{CO} + 2\text{NaOH} = \text{Na}_2\text{CO}_3 + \text{H}_2\text{O} + \text{CO}$$

Test the gas collected, after taking out the bottles one at a time, by using a lighted splint, removing the cover glass at the time. Test with linemwater the product of combustion, some of which is left in the receiver.

What color did the flame have? Is the gas a supporter? Is it a combustible?

On detaching the apparatus burn the gas in the generator, all bottles, carefully avoiding inhaling any.

(To be continued.)

WILL THE GERMANS BOMBARD NEW YORK?
(Continued from page 157)

The New York Department also knows the exact whereabouts of its own submarines, and the propeller sounds of our own ships as well as the sounds of our own submarines, can thus be eliminated. Should the message be that a certain prescribed route, then the work of the listening-in operator would be vastly simplified.

By means of a subaqueous defense of this kind, it would become an easy matter for the Navy Department to practically make it impossible for the German submarines to break thru the defense unnoticed. In that case it would of course be impossible for the German submarines to assemble their aeroplanes and the attempted raid would be frustrated before it got well under way. A defense of this kind would not be very costly, and it is certain to be practical. Microphone buoys of this kind are usually located from thirty-five feet to fifty feet below the surface, as near the path of the possible enemy as possible. When the wave motion on top of the ocean will not interfere with the microphones, as at this depth no sound from above reaches them.

On the other hand, these buoys being only small affairs, and being submerged so deeply are quite unseen and unnoticed by the enemy who does not know their whereabouts, this being known only to the Navy Department.

The writer is confident that a device of this kind would help us towards the elimination of the submarine menace, which only fools deny exists.
THE ORACLE
(Continued from page 190)

be demagnetized is that of mechanical shock, and this should be avoided as much as possible.

BOOK ON DESIGN OF ELECTRO-
MAGNETS
(936) J. Morton, Wilmington, Del., asks:
Q. 1. What good book can you recommend on the design of electro-magnets?
A. 1. We can furnish a very good book on the design of electro-magnets and solenoids at $2.15 prepaid, entitled "Solenoids and Electro-Magnetic Windings," by Underhill.

MEANING OF D. S. C. AND S. S. C.
(937) Harold Wenzatz, Box 165, Rose, N. Y., inquires:
Q. 1. What is the exact meaning of magnet wire designations, such as D. S. C. and S. S. C.?
A. 1. With reference to the terms "D. S. C." and "S. S. C." would say that D.S.C. stands for double silk covered magnet wire, while S.S.C. stands for single silk covered magnet wire. In the trade the term wire is usually dropped now-a-days, the wire being termed simply "D.S." wire, etc.

SOLENOID DATA.
(938) N. W. Petefish, La Cygne, Kansas, wishes data on building a small solenoid.

ELECTRICITY
9' Vols. Flexibly Bound Pocket Size

Typical Design of Solenoid Or Suction Type of Electro-Magnet.

A. 1. We give details herewith necessary for the construction of an electro-magnet capable of lifting 8 lbs., thru a distance of 4".

Wind about 6 lbs. of No. 14 D. C. C. wire on the spool shown in the accompanying diagram, and then enclose this winding with very soft iron, of the dimensions shown. It is to be noted that the plunger will always be in its socket about 1" deep, the reason for this being that a larger pull is given at the start, than were the plunger to be merely at the end of the coil.

LAMP BANK AND ELECTROLYTIC INTERRUPTER.
(939) Clifton A. Sibley, Salem, Mass., asks:
Q. 1. Can I not use a lamp bank instead of an electrolytic interrupter on a 110-volt circuit with good results?
A. 1. Your assumption in using a bank of lamps in place of an electrolytic interrupter is entirely wrong. The function of the interrupter is to interrupt the current many hundreds times per second, and it accomplishes this by having a bubble of gas form at one of the electrodes which constantly breaks, and as you can see when this happens a circuit is made.

The reason why lamps are put in a circuit is solely to control the amount of current flowing thru the circuit.

Be guided by a Practical Man

Be guided in your study of electricity by an experienced Electrical Engineer of high professional standing. Terrell Croft, author of 1 of these volumes, climbed from the ranks to Electrical Engineer with the Westinghouse Company. He gained his knowledge with his knees rolled up and has met your problems in advance. He tells in plain, understandable language how to proceed by the best and most practical methods.

EASY PAYMENTS
For the course as you go along, $2 per month represents an achievement parallel to mechanical wonders. The terms are so easy that you may easily afford a training which will prepare you in a short time to take a more responsible, better paid position.

Just Send the Coupon

The coupon below is for your convenience. In examining these practical books, it obligates you in no way, on the other hand, it may easily prove to be the means of acquiring the additional practical knowledge you will need.

Fill out and forward this coupon—and receive the entire 6 volumes in parcel post or express prepaid for 10 days free examination. If, after examining them, you are not convinced of their power to help you in the higher positions in the field, send $2 to ten days and the book back at the rate of $2 per month until $16 has been paid.

ELECTRICAL EXPERIMENTER.

July, 1918

WIRELESS SALE

On April 6th of last year, when war was declared, we had made preparations to give our patrons wonderful service and had imported an enormous stock of our most popular wireless instruments below mentioned. We desire to reduce this stock to the extent of $6,000, still retaining a big reserve when the wireless stations reopen. To accomplish this, we have just slaughtered the prices. Remember that during the past year wireless keys and everything electrical has increased tremendously and it is an absolute certainty that wireless instruments manufactured with an eye to war is over in less than greatly increased prices. The demand will be so terrific that thousands will have to wait months for their instruments. Many are now getting their stations ready. This is your opportunity. When this stock is reduced adequately further orders will be accepted and remittance will be returnable.

WIORAY Portable Therapeutic LAMP

For Home and Professional Use

Unexcelled for the treatment of skin diseases, cuts, bruises, and sore muscles. Takes the place of the hot water bag and gives more penetrating and satisfactory results. Highly recommended by the Medical Profession.

Reflector specially designed to diffuse the rays thereby covering a large area without a focused beam.

TWO SIZES

7 inch, $5.00-8 inch, $6.00

For sale at all leading surgical supply stores and dealers. Be sure to specify the WIORAY. Manufactured by The Oak Mountain MFG. Co., 915 Whitelock Ave., Bronx, N. Y.

PHOTOGRAPIER'S

Portable High-Frequency and X-Ray Apparatus.

MILESTONES IN THE LIFE OF THOMAS A. EDISON.

(Continued from page 161)

great plant at West Orange, N. J., was the scene of a great conflagration. Early next morning gangs of men were at work clear in up the debris. Here we find the model laboratory. Where we added during the day and work was continued 24 hours a day. Within 36 hours after the fire Edison had given full orders for the complete reorganization of the plant.

Early in the year 1915 Edison found that he was in danger of being unable to obtain a continuous supply of metal wire which he made his synthetic carbide. He de-

ected to erect his own benzol plants. He experimented and erected it in his laboratory at Orange, N. J., and was obliged with two coke oven plants to put in his benzol plants. The first was installed at the Cambria Steel Company's plant at Johnstown, Pa., which was installed and put into op-

eration in 45 days. Four other plants have since been installed.

The same year Edison conceived the idea of helping the textile and rubber industries of America by making myrbane, aniline oil and synthetic rubber, which was imported from Germany. With much effort and hard work, he installed a plant in 45 days, commencing deliveries in June, 1915. He is now manufacturing 4,000 pounds a day.

1917-

Since the United States entered the war, Mr. Edison has been constantly cooperating with the United States Government in various experiments, making them at Orange, N. J., and elsewhere.

U. S. WANTS RADIO INSPECTORS.

The United States Civil Service Commission announces an open competitive examination for radio inspector, for men only, Vacancies in the positions of radio inspector and assistant radio inspector, at entrance salaries ranging from $1,200 to $1,600 a year, depending upon the qualifications of the applicant. The appointment of the radio inspectors of the Bureau of Navigation, Department of Commerce, in Washington, D. C., and the States, will be filled from this examination.

Competitors will not be required to report for examination at any place, but will be required to report to the Bureau of Navigation, 100 F Street, N. W., Washington, D. C., at a time and place to be fixed, and will receive the relative weights indicated: 1. Physical ability, 10; 2. Education, training, and experience, 90; total, 100.

Under the second subject competitors will be rated upon the sworn statements in their applications and upon corroborative evidence of additional qualifications.

Applicants must have had the training and experience specified in one of the following groups:

(a) Completion of a high school work (usual two years), and in addition not less than one year's experience in the special radio work such as the manufacture, installation, or adjustment of commercial or governmental wireless apparatus.

(b) Completion of a college or university of recognized standing, having pursued for at least two years, courses in radio and kindred sciences, such senior students being required to submit with their applications their furnishing proof of actual graduation within three years from the date of making oath to the application.

Applicants must have reached their twentieth birthday on or before the date of the application.

Applicants must submit with their applications their photographs, taken within two years, with their medical examination, and the fees will not be accepted.

Applicants will be admitted to their examination regardless of their residence and domicile; but only those who have been actually domiciled in the State or Territory in which they reside for at least one year previous to the date of making oath to the application, can be admitted to the examination. The government's certificate in the application form executed, may become eligible for appointment to the appropriated service in Washington, District of Columbia.

On account of the urgent needs of the service, applications will be received and finally notice. Papers will be rated provisionally and the exami- nation made as the needs of the service require.

This examination is open to all male citizens of the United States.

Applicants should at once apply for Form 1312, stating the title of the position in the Civil Service Commission, Washington, D. C.; the duty and nature of the work to be done in the office of the Bureau of Navigation, the pay, and the place of residence. Many of the former officers' certificate in the application form executed, may become eligible for appointment to the appropriated service in Washington, District of Columbia.

On account of the urgent needs of the service, applications will be received and finally notice. Papers will be rated provisionally and the exami- nation made as the needs of the service require.

This examination is open to all male citizens of the United States.

Applicants should at once apply for Form 1312, stating the title of the position in the Civil Service Commission, Washington, D. C.; the duty and nature of the work to be done in the office of the Bureau of Navigation, the pay, and the place of residence. Many of the former officers' certificate in the application form executed, may become eligible for appointment to the appropriated service in Washington, District of Columbia.
$5.

**EXPERIMENTS!**

**Student's Chronic Plunge Battery**

This is an ideal battery for electrical experiments where a small but powerful current is needed for testing purposes. In no case will this battery hurt any circuit or apparatus. Each battery contains 2 cells and requires no care. Each cell contains 25% of the entire battery weight.

- **No. 1:** 2 Vols. 1.50
- **No. 2:** 2 Vols. 3.50
- **No. 3:** 2 Vols. 5.00

**The “Electro” Radiotone**

**HIGH FREQUENCY SILENT TEST RUZZER**

An instrument of ideal pitch and range, produced with high precision. It is particularly useful for testing purposes. Each instrument contains a complete set of frequencies. Adjustments can be made to the instrument for testing purposes.

- **No. 1:** 1.00
- **No. 2:** 2.00
- **No. 3:** 3.00

**The “Electro” Telegraph**

Is not a toy, but a practical, honestly built telegraph instrument, which can be sold and used like the big commercial instruments. By studying the directions and practicing for a few days, you will be able to build a home telegraph. Each operator is in big demand now. The instruments are for home use and are complete for 2 Vols. 1.00.

**The “Electro” Codophone**

(Patent Pending)

For sending and receiving telephonic messages. It is not a toy, but a practical instrument that can be used for telephonic communication. Each instrument contains a complete set of directions. For sending and receiving telephonic messages, it is an ideal instrument.

- **No. 1:** 1.00
- **No. 2:** 2.00
- **No. 3:** 3.00

**The “Livest Cables in America!”**

Our big, new electrical cables are described in the catalog. Positively the best. Print, Digest Covers, 250 illustrations, 327 pages.

**DIAL PHONE RINGING**

The dial phone ringing is a useful tool for telephonic communication. It is a practical instrument that can be used for telephonic communication. Each instrument contains a complete set of instructions.

- **No. 1:** 1.00
- **No. 2:** 2.00
- **No. 3:** 3.00

Colonel Carty Receives Edison Medal.

(Continued from page 173)

the U. S. Army. If General Pershing has his way, Carty will be a General before many a day. General Pershing understands that Carty is made of stuff of which great generals are made."

John Joseph Carty was born at Cambridge, Mass., on April 14, 1861. Nature endowed him with a clear, keen mind, a liking for mechanical experimentation and an infinite capacity for work. He was graduated from the Cambridge Latin School and intended to enter Harvard University, but was put out by a serious trouble with his eyes, which made it impossible for him to prepare for the college entrance examinations.

He became interested in the telephone, then a new scientific device unappreciated by the majority of persons, and in 1879 started work in the Bell System with the Telephone Dispatch Company of Boston. In 1887 he took charge of the Western Electric Eastern Cable Department, and later of the Western Electric Eastern Switchboard Department. In 1890 he became Chief Engineer of the New York Telephone Company, then the Metropolitan Telephone and Telegraph Company, and while in this position, twice directed the technical work in connection with the reconstruction of this company's plant, once when the system was changed from ground circuit to metallic circuit, and the second time when it was changed from local battery to common battery.

Colonel Carty's honors are almost as numerous as his contributions to the science of telephony. He received the degree of Doctor of Engineering, from Stevens Institute of Technology, in 1915; Doctor of Science from the University of Chicago and Bowdoin College in 1916; Doctor of Laws from McGill University in 1917. In 1903 he received the Edward Longstreth Medal from the Franklin Institute of Pennsylvania, and in 1916 the Franklin Institute bestowed upon him its highest honor, the Franklin Medal, "in recognition of his distinguished service to mankind rendered in the field of Science."

For his service in connection with the establishment and development of the telephone system in Japan, Colonel Carty twice received the formal thanks of the Japanese Imperial Government, was decorated by the Emperor of Japan in 1909 with the Imperial Order of the Rising Sun, and in 1912 with the Imperial Order of the Sacred Treasure of the Meiji.

Colonel Carty is a past president of the American Institute of Electrical Engineers, of which he has been a member since 1890, and a fellow since 1913. He is Chairman of the Executive Committee of the National Research Council, a trustee of the Carnegie Institution of Washington, a past president and life member of the New York Electrical Society, a fellow of the American Academy of Arts and Sciences, a fellow of the New York Academy of Science, and an honorary fellow of the American Electro-Therapeutic Association. He is a member of the Society for the Promotion of Engineering Education, the Franklin Institute, the American Society for the Promotion of Industrial Education, the American Physical Society, the Franklin Institute of Philadelphia, the American Association for the Advancement of Science, the Society of Arts of the Massachusetts Institute of Technology, the Telephone Pioneers of America, the Association of Railways and Telegraph Superintendents, the American Geographic Society, and various telephone societies.
Fulminates.
(Continued from page 185)
active substances, since it would tend to increase the temperature of the flask by burning the carbonic oxide into carbonic acid, and would thus increase the ignition of the cartridge. For military caps, in this country, potassium chlorate is always mixed with the pressed, red-mercuric glass, sometimes added to increase the sensibility of the mixture to explosion by percussion. Antimonium sulfitum is sometimes substituted for antimonious glass, apparently for the purpose of lengthening the flash by taking advantage of the powerful oxidizing action of potassium chlorate upon that compound. Since the composition of the mixture is very liable to explode under friction, it is made in small quantities at a time, and without contact with any hard substance.

If a thin train of mercuric fulminate be laid upon a plate, and covered, except a little at one end, with gunpowder, it will be found on touching the fulminate with a hot wire, that its explosion scatters the gunpowder, but does not inflame it. On repeating the experiment with a mixture of 10 grains of fulminate and 13 grains of potassium chlorate (mixed upon paper with a card), the explosion will be found to inflame the gunpowder. (See Fig. 1.)

By sprinkling a thin layer of the fulminate upon a glass plate, and firing it with a hot wire, the separated mercury may be made to coat the glass, so as to give it all the appearance of a looking-glass. (See Fig. 2.)

Altho the effect produced by the explosion of mercuric fulminate is very violent in its immediate neighborhood, it is slightly felt at a distance, and the sudden expansion of the gas will burst fire-arms, because it does not allow time for overcoming the inertia of the ball, tho, if the barrel escape destruction, the projectile effect of the fulminate is found inferior to that of powder. It has been proved by experiment that the mean pressure exerted by the explosion of mercuric fulminate is very much lower than that produced by gun-cotton, and only three parts of that produced by nitro-glycerin. Its great pressure is due to its instantaneous decomposition into CO, N, and H20, and its power within a space not several times greater than the volume of the fulminate itself, which volume being very small, on account of the high density of the fulminate, the escaping gases exert an enormous pressure at the moment of explosion.

This detonating property of mercuric fulminate renders it exceedingly useful for effecting the detonation of gun-cotton and nitro-glycerin. Berthellot finds that even such stable gases as acetylene, cyanogen and nitric oxide are decomposed into their elements by the detonation of mercuric fulminate. Mercuric fulminate is generally contaminated with mercuric oxide, which is one of the secondary products formed during its preparation.

Fulminate of silver.—Silver fulminate is prepared by a process very similar to that for fulminate of mercury: but since its explosive properties are far more violent, it is not advisable to prepare so large a quantity. 10 grains of silver are dissolved at a gentle heat, in 70 minims of ordinary concentrated nitric acid (sp. gr. 1.42) and 30 minims of water. As soon as the silver is dissolved, the lamp is removed, and 200 minims of alcohol (sp. gr. 0.87) are added. If the reaction does not commence after a short time, a very gentle heat may be applied until effervescence begins, when the fulminate of silver will be deposited in minute needles and may be further treated.

Learn Aviation Mechanics. "Supremacy in the air the Key to Victory!"

We are the Pioneer Aviation School.

"Look at Him Today!"

Six years ago he started in here just as you are doing. Now he's General Manager and makes more in a day than he used to make in a week. I'll tell you how he did it. The first week he was here he began to train for the job ahead by studying in spare time with the International Correspondence Schools. Inside of six months he got his first promotion. But he kept right on with the I. C. S. I tell you a man like that is bound to get ahead. Some day he'll be President of the Company. You've got the same chance he had, young man, and if I were you I'd follow his example. Take up some I. C. S. Course and do it right away. Use your spare time. Study. What you are six years from now is entirely up to you.

This is the story of thousands of successful men. They did their work well, and in spare time, with I. C. S. help, trained themselves for advancement. That's the thing for you to do. Whatever your chosen work may be, there is an I. C. S. Course that will prepare you right at home for a better position with bigger pay. More than 100,000 men are getting ready for promotion right now in the I. C. S. way. Let us tell you what we are doing for them and what we can do for you. The way to find out is easy. Just mark and mail this coupon. It won't cost you a cent or oblige you in the least, but it may be the first step toward a bigger, happier future. Don't lose a minute. Mark this coupon and get it into the mail right now.

ELECTRICAL EXPERIMENTER

July, 1918

as in the case of fulminate of mercury. (Note.—If the fulminic acid and alcohol are not of the exact strength here prescribed, it may be somewhat difficult to start the action unless two or three drops of red nitric acid [containing nitrous acid] are added. Standard silver [containing copper] may be used for preparing the fulminate.) Silver fulminate is also prepared when nitrogen is more than just sufficient to form an alcoholic solution of silver nitrat. When dry, the fulminate must be handled with the greatest caution, since it is exploded far more easily than the mercury salt; it should be kept in small quantities, wrapped up separately in paper, and placed in a cardboard box. Nothing hard, sharp, or pointed should be em-
ployed in manipulating it. The violence of its explosion renders it useless for per-
cussion caps, but it is employed in detonating cracker.

THE STORY OF A POUND OF COAL

(Continued from page 158)

power. Thus the electrical energy put into the lamps we only receive five per cent in the form of radiant light,—the other 95 per cent is lost. Lost, all because we of to-day do not know enough to more effi-
cently convert electric current into radiant light. At the present energy consumption of 1 watt per lamp a tungsten lamp is sioning on the perfect idea of a transformation of the energy in one pound of coal, viz., 14,150 B. T. U. we would get (14,15 x 293 kilo-
wait-hour) (4,145 K.W.) or 14,15 candle-
power, as represented by the large lamp at the right of the illustration. As a matter of fact we only manage to get 1.45 x 293 K.W.

Analysis of Average Losses in Conversion of One Pound of Coal Into Electricity.

in, Ky., and the five young Home Spun. I wish I had rather have your Tobacco than all the manu-
factured in the world. I only said your Tobacco.

If you will try my OLD KENTUCKY HOME SPUN you will be glad and want more for the sensational equal it shows. Kentucky has the best.

RUBLE McNeLL, Boss, Kentucky

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.
Fig. 1 shows the form of the light curve of Algol. In an unvarying period of 24.20 ^{h} 48^{m} 59^{s} the light of this star goes thru a cycle of change. During most of this time its light is nearly constant, but suddenly within 4 hours it rapidly declines until it has lost 64% of its original brightness. It remains at this minimum brightness (A1 in Fig. 1) for about twenty minutes and then rapidly rises to its original value in 3 hours. For a long time it was impossible to detect the secondary minimum (A2 in Fig. 1), but finally by attaching a selenium cell to the telescope, which device is particularly susceptible to light changes, the position of the secondary minimum midway between the principle minima was located. An examination of Fig. 3 will explain the nature of the light changes of Algol.

A1, A2, A3 and A4 are positions of the bright star in its orbit and a, b, c and d are corresponding positions of the dark star. The two stars are always in line with c, the center of gravity of the system. When the faint star is in the position a, it shuts off 64% of the light of a by partially eclipsing it (the two orbits are not in the same plane). When at a, the faint star is itself eclipsed by A in the position A4. The extremely small amount of the decrease in light from the systems when the stars are in this position (see Fig. 1, A4) shows how feeble the light of a. The amount of light shut off when a is eclipsed is inappreciable to the eye directly and is only recorded by the sensitive selenium cell. It was formerly believed that the star was totally dark. In the positions A1, A2, A3 and A4, the light from the system is a maximum, as it comes freely from both stars.

Fig. 2 shows the shift of four dark lines in the spectrum of Algol (the dark absorption lines of hydrogen). The spectrum taken under a too faint to give a visible spectrum and but one set of lines is seen. The normal spectrum of A is at the top (Fig. 2) and corresponds to the position A1. The position of the lines in A1 is also normal. In these two positions the radial velocity—that is, velocity in the line of sight—towards or away from the earth is zero. The motion of a star in its orbit is at right angles to the line of sight at any point; so at A1, A2 the bright star is moving across the line of sight or direction to the earth which is assumed to be toward the bottom of the page. At A3 (see Fig. 3) the star is moving at greatest speed toward the earth and the lines in the spectrum have their greatest displacement toward the violet end of the spectrum. At A4, the star is receding at greatest speed from the earth and the displacement is greatest toward the red.

The amount of these displacements measures the velocity of Algol in its orbit, after the radial velocity of the system as a whole thru space is allowed for. The total period of the shift in the lines and the period of light variations are the same, showing conclusively that Fig. 3 represents the true conditions that exist in this system.

From the duration and amount of the variation of light and the spectroscopic evidence the following facts are known respecting this system: The two stars are nearly equal in size, the dark companion being slightly larger. The distance between the centers of the stars is about 4.8 times the radius of the bright star. The surface brightness of the bright star is nearly constant, the surface brightness of the principal star and its density is slightly less. The density of Algol, the light star, is only 1/8 of the density of our own sun and its diameter is a little OVER ONE MILLION MILES. Its velocity in its orbit determined by the displacement of its lines is 260 miles per second and the orbital velocity of its companion must be about 60 miles per second.

**SEND NO MONEY USE THESE ELECTRICAL BOOKS SEVEN DAYS AT OUR EXPENSE**

By merely filling in and mailing the coupon below you can get this complete set of the Cyclopedi of Applied Electricity on trial. Pay only small shipping charges when they arrive. Use these books for seven full days before you make up your mind whether or not you want them. If you keep them, you may pay the special advertising price in easy installments of $2.00 a month. If you don't want them, you may send them back at our expense and you won't be out a penny.

**A MASSIVE ELECTRICAL LIBRARY—NOT HANDBOOKS**

These seven splendid volumes contain all the knowledge you need in order to earn big money in the electrical field. They are not thin handbooks, but thick, encyclopaedia-size volumes, handsomely bound in half morocco leather, gold stamped. Each one measures 7 by 10 inches, and is 2 inches thick.

This big size permits the use of large and comprehensive illustrations, plates, diagrams, etc. Over 3,000 cuts are contained in the Cyclopedi's 3,500 pages.

The completeness of the Cyclopedi will be a revelation to you. Everything electrical is explained in plain, simple English—every technical point is made clear. Each volume is carefully cross-indexed for instant reference.

**50c a Week** For this sum—an insignificant one—this wealth of electrical information is yours. But you don't have to send us a penny until you have used the books for seven days. Then, if you decide to keep them, send only $2.00 a month—50c a week—until the special advertising price of $19.80 has been paid. The regular price of these pay-raising books is $35.00.

**Consulting Service Free** A year's Consulting Membership in the American Technical Society—regular price $12.00—will be included with all orders for a limited time. The advice of an entire corps of electrical experts is yours to help you in your progress— for a whole year FREE!

**Send No Money—Just the Coupon**

See these books for yourself before you buy. Remember, you don't risk a penny or assume a single obligation. The books will be sent to any one within the boundaries of the United States or Canada, and they may be returned at our expense if you fail to please. But you must act now! This generous offer cannot be continued indefinitely. Send the coupon now.

HUMANIZE YOUR TALKING MACHINE

PERHAPS you, like thousands of others, would like to overcome that harsh, metallic grating sound that destroys more than half the value and enjoyment of any record. Just the minute you put on the

ELLIS MELODIOS REPRODUCER

you will realize that you have been missing the real music. You will take renewed delight in playing over your favorite records with a keen pleasure never known before.

The Ellis Melodious Reproducer is the one thing that has been needed to perfect the phonograph—a sound box that will perfectly reproduce the living voice of the artist and bring out all the subtle tones of instrumental music.

Rest assured, this Reproducer obliterates all that harsh "twang." It softens the "clash" and puts harmony into every word and note.

It reproduces the "living voice" or the perfect instrumental tones of the artist who made the record. Hearing is believing.

FITS ALL STANDARD MACHINES

The Ellis Melodious Reproducer plays perfectly all disc record selections and is adapted for all makes of disc phonographs.

Steel, fibre or any type of needles will work perfectly. As the weight is less than four ounces, records wear indefinitely.

Every reproducer is fully guaranteed for 5 years. Write for circular No. 9.

J. H. ELLIS, Post Office Box No. 882, Milwaukee, Wis.

High Frequency Bargains

In taking our inventory we found over 200 Violet-Ray machines of all makes. We selected 100 of the best machines, which we thoroughly overhauled in our factory making them better than new. Many of these machines cost over $40.00.

We have placed all these instruments in two groups and are disposing of them for the ridiculously low price of $9.75 and $12.50.

How to secure one of these machines

Send only 50 cents to pay express charges and we shall send you one of these instruments by express for your examination. This amount will be deducted from total cost of machine. You need not accept if not satisfactory.

Send at once for we shall send the best machines out first and the quicker you send in your order, the better machine you will get.

We shall also send our beautiful booklet "Violetta" describing the many uses for the high-frequency currents of Violet-Ray machines. A perusal of this booklet will afford you much information and will be of much assistance to you.

L. C. Smith

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.
A considerable variety of screens is used according to the nature of the radiation required. The gamma rays are extremely penetrating and are somewhat analogous to the very penetrating Roentgen rays. In all instances the effects, and penetration depends on all three factors:—the amount of radium used, the filtration and the distance in which the screen is set from the tumor and the depth of the tumor, or other growth.

Secondary rays. The use of thick screens of heavy metal is accompanied by the production of secondary rays, capable of causing considerable surface irritation. They may be absorbed by the use of many layers of black paper or thick rubber tubing.

Duration of Applications (Exposures). Very short exposures of 1 to 10 minutes are given for treatment of superficial skin troubles. The applicator is applied without any screen behind that afforded by a thin rubber screen. Short exposures of 15 minutes to one hour are frequently resorted to when treating warts, ulcers, etc. The screening of these exposures rarely exceeds 0.02 mm. of copper. Occasionally long exposures of 1 to 12 hours are adopted when it is desired to obtain the destructive action of the rays, used in cases of rodent ulcer, rapidly growing epithelium lupus vulgaris, etc. Exposures of 3 hours duration and upwards are usually spaced over a period of two or three days, and no screening or a screening of 0.1 mm., lead is employed.

Prolonged exposures of twenty to one hundred hours are used in the treatment of deep-seated malignant growths; lead screens are always used, usually of 2 mm. thickness, exposing the patient in periods of six to twelve hours with an interval of at least twelve hours between successive exposures.

The Reaction. All tissues when treated with Radium respond in some manner, but the nature and extent of this response varies greatly, depending upon the particular apparatus, the amount of Radium employed, the nature of the tissue treated and the conditions of the tissues treated.

Factors in treatment to be considered are age, sex, temperament and susceptibility to actinic rays. The reaction usually appears between the seventh and fifteenth days, and four or five exposures are at least distinguished; simple erythema, Erythema followed by desquamation, Vescication with superficial ulcerations and deep ulceration, sometimes accompanied by the production of eschar are seen.

All kinds of opinions may be drawn from the reports of cancer experts and various statements appearing from time to time in newspapers, but preference should be extended to those who have had most experience in handling and applying Radium. One thing is certain and that is that a larger amount of recoveries and cures have been noticed with larger quantity application of rays and performance in the majority of hospitals have only very small amounts of the element. By this I do not mean that Radium in smaller quantities is not capable of doing a great amount of good but until we acquire experience and make a larger, broader and more universal practice of it's use, thereby acquiring more and more experience, it is not possible to receive all the benefits that undoubtedly lie apparently just behind a thin veil of mystery. Therefore while the greatest good is accomplished in general it seems, where the quantity of Radium applied is thoroly powerful enough to affect the growth or already being treated.

One of the easiest things to make is a pinhole camera. The essentials of nothing else than a box with a pinhole in the front and a ground glass screen on the side opposite, the back.

Answer Your Country's Call
The Government Is Calling
for experienced wireless operators and telegraphers. Prepare to serve
where needed the most—learn at home to be a proficient operator.

Telegraph and Key

Outfit consists of a telegraph key, buzzer and three binding
posts, mounted on a finished base, 7 in. x 4½ in.
The key has silver contact points and "click" for learning to
send messages in the Morse American Code. The buzzer repro-
duces the sound signals used in wireless.
The key may be used alone or with the buzzer, and two Outfits
placed at some distance apart can be operated for
sending and receiving practice.

Price, complete with wiring diagram and code
chart

$2.00

Knapp Combination Wireless Outfit

For Learning
Sight and
Sound Signals,
Wireless and
Land Lines.

This Outfit is similar to the Knapp Buzzer and Key Outfit No. 405, with the
addition of a Lamp, Lamp Socket and Control Switch.

Two dry cells connected to the binding posts will produce the necessary bright
flash from the lamp, which is operated by the key for sight signalling; the Buzzer,
operated by the Key, gives the wireless sound signals; while the Key, without
buzzer or battery, may be used for American Morse Code practice.

Two Outfits may be operated at
a considerable distance apart.

Price, complete with wiring
diagram and code chart

A NEW ELECTRIC RECORDING
COMPASS.
(Continued from page 165)
to realize the benefits which they could ob-
tain from its installation aboard their ves-
sels, but on the part of the officers of the
ships. Their arguments against the inven-
tions were not direct; they merely rested on
the statement that they did not know
what they termed a "mechanical spy" on
board.

A record made by the instrument during
this period, while on a cruise up Long
Island Sound, is given herewith.

The recording compass, as its name im-
plicates, is a device which will make a di-
nuous record on a sheet of paper whatever
courses the ship may have taken during a
cruise of any duration.

By the addition of other quite simple at-
tachments, the speed of the vessel during
any interval is shown as well as the number
of revolutions of the engine and also what-
ever signals affecting the movements of the
ship which may have been given. All this
data is plotted automatically on a chart
against time.

In the event of any controversy arising
as regards the movements of the ship these
records would serve to establish the justice
or injustice of unkind criticism; and they
would be invaluable for purposes of de-
termining the relation of the speed to the
revolutions since they show precisely what
progress the vessel made at all points. In
cases when "dead reckoning" must be re-
sorted to, a record of the behavior of the
ship since she left harbor would eliminate
all risk from error and place this process
upon a scientific basis. In legal actions
based on the movements of ships, as in colli-
sion during fog, etc.; the records would
serve to show whether due caution had been
exercised and hence would fix the re-
sponsibility. The operating office would
be able, by a precise record showing whether
their orders as regards the man-
uevering of their ships had been executed;
whether the pilots were properly per-
forming their duty, etc. The value of the in-
strument for exploration purposes is readily
apparent.

The invention consists of a spark coil
capable of producing a disruptive discharge
thru one inch and of the usual ship bin-
nacle excepting that the needle is attached
to a very light aluminum spiral, with a
diameter of 1 inch, as herewhith; below the compass is a
compartment aluminum spiral a paper chart is fastened to a circular frame. This frame is slowly
revolved by means of a step by step me-
chanism which is visible in the illus-
ration. The gearing being actuated period-
ically by a master clock, a new circular motion is imparted to the chart
equivalent to 5 degrees (one small angular
division) per hour. The chart frame has a
radial conductor to which one secondary
terminal of the spark coil is attached, the
other terminal is connected to the aluminum
spiral thru the center support. A stream of sparks passing from the conductor to the aluminum spiral will perforate
the paper record which is interposed between
them. The aluminum spiral is held in a
constant direction by the directional force
exerted by the needle, while the chart
changes its angular position with respect
to the needle as the ship changes its course.
This change in angular position produces a
change of the point of intersection of the
radial conductor and spiral. Perforating
the paper by an electric spark, which will
jump thru it at this intersection point, re-
sults in a record of the behavior of the
ship as regards direction.

The spiral is arbitrarily selected so that
at the north end of the compass it is three
inches from the center, at the west point
the radius vector is two and one-half inches
at south two inches and at east one and

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.
one-half inches. The spiral recedes uniformly from the center at all points, hence it is the Spiral of Archimedes. From the equation of the curve $r = a \theta$, derived from the principle of instantaneous geometry, a very accurate construction of the spiral is possible.

The chart is provided with three circles spaced one-quarter of an inch apart in which are recorded the speed of the vessel, the number of revolutions of the engines and various signals which may have been given. These records are made in the same manner, that is by electrical perforation. Connection to a standard taffrail log, which may be so arranged that an electrical circuit is completed every knot or multiple thereof, affords the means of recording the speed. The number of perforations in the hour division gives a measure of the speed in knots per hour. In the same way the number of revolutions of the engines per hour is recorded. A standard revolution counter may be so connected that every ten, hundred, thousand or ten thousand revolutions are recorded on the chart. Connection could be made to the sounding devices and these recorded on the same chart.

Here is a drawing of the spiral, the radial conductor which extends under the compass reach from the flower de lis to the center and the record chart, all located in the same relative positions which they occupy in the machine. It is apparent that the distance which the spiral cuts from the flower de lis or north end of the compass box varies as the angle, and in as much as it is this distance which is indicated by means of the electric discharge upon the paper, a continuous record of the past behavior of the compass is obtained. An actual record of a cruise up Long Island Sound on board Dr. Jaeger’s private yacht, the Reco, is here reproduced. The chart reveals the fact that the yacht put out of port pointing S.E. and held this course for about an hour; in approximately fifteen minutes the course was changed to E. by S. and held for forty-six hours; at this point the course was changed again, N.E. by N., the change requiring one hour and a quarter, following this in six hours time the course N.E. was pursued for the remainder of the trip of twelve and one-half hours duration.

The yacht was a sailing vessel on which no engines were running, neither is there a log record hence the only information we can obtain from the chart is that it required forty-six hours to go out, six and one-half hours to partially reverse its direction and eighteen and one-half hours to put into port. The helmsmanship was good, since there are no abrupt changes in the trace of the course and furthermore one could gather that the sea was running fairly quiet, since the yacht being of small tonnage and draft would, in rough water, be forced into different courses, frequently resulting in an irregular record.

The view of the cabinet and apparatus shows the sundry special relays, controlling devices, switch gear and the various mechanisms which are necessary for the proper functioning of the recording compass. From its comprehensiveness the reader may obtain a general idea of the vast scope of labor which was entailed in its construction.

Upon first thought it may seem as tho the magnetic needle would be affected by the electric spark which is in such close proximity. Microscopic examination of the needle while under such influence shows no effect whatever. This is explained because of the fact that the magnitude of the current is very minute or about two milliamperes, and also because the spark is an irregular current of high frequency, consequently the resultant magnetic field would be practically zero.

(Continued on page 206)
War Inventions Wanted

War will repeat itself in the present War. The greatest victories will be won, and through corresponding simplicity, lost through the unnecessary. The individual inventor should not be discouraged by the War. The Special War Bulletin puts upon the press a good idea of what is needed. We will send it to you free of charge. Located in Washington, we are in close touch with the proper Government Officials who will be prepared with inventions for use in War, and we will advise you fully how the disclosure should be made.

Soon, we plan with an inventor or manufacturer to establish his rights before sending a sketch, drawing or model to any attorney. Second, to give a frank opinion as to what will pay to patent. It is the idea, based upon a useful and practical apparatus, that assures the person the patent. Third, to obtain for him a reasonable term of protection and prevent it from being offered for sale to the public. If you are an inventor, you will find that the chance of profit is not only safe, territorial, but obtains royalty, or the independent manufacturer of the invention.

Before disclosing the invention to anyone, sign, witness and deposit in our safe, safe the form, "Evidence of Concepcion," and establish Uncle Sam's claim in our book. Kindly read carefully the how to protect your invention. (Send for them on a post card of simply mail coupon below.

E. H. TALBERT

Invent Something

YOUR IDEAS MAY BRING WEALTH IF PATENTED

Now is the time to patent a meritorious invention. We are constantly receiving letters from manufacturers and inventors interested in new inventions protected by patents secured through us and which can be turned into money through proper handling.

Write us today for free copy of our 164 page book "How to Get a Patent and What to Invent." At the same time send us a sketch photograph with written description of your invention for our FREE PATENT OPINION and Evidence of Conception Certificate. If your invention is proper subject matter for a patent we will send you our Certificate to that effect.

TALBERT & TALBERT, 4287 Talbert Building, Wash., D. C.

Pocket Wireless.

(237) Robert N. Rose, Queens, N. Y., submits an idea to put a complete wireless outfit, phones excepted, in an ordinary book, which is connected to a rotary rectifying switch operated by a synchronous motor, run by current from the main, supplying the primary of the transformer. This is connected to an electro plating outfit. Our correspondent wishes to know if this idea is patentable and practicable.

Electro Plating.

(236) Robert McGib, Chicago, Ill., wants our opinion as to the patentability of a combination of a transformer, the primary of which is connected to the main, and is connected to the secondary of which is connected to a rotary rectifying switch operated by a synchronous motor, run by current from the main, supplying the primary of the transformer. This is connected to an electro plating outfit. Our correspondent wishes to know if this idea is patentable and practicable.

A. There is nothing very new about an idea of this kind, and it is certainly not patentable. Furthermore, we very much doubt if good plating will result from a combination of this kind, for the reason that a system of this kind will not deliver pure direct current necessary for good plating work.
Submarines, torpedoes, flying machines, machine guns, immense howitzers, the British "tank" and the, and an untold number of other products of American brains, are dominant factors in the Great War. We are just starting, our—YOUR—ingenuity must lead to Victory. Uncle Sam—the whole civilized world—that will aid in the fight. Can't you help with even ONE of thousands of simple things that will win recognition—perhaps fortune for you.

The need is for inventions of peace, too. Never before was there such a demand for new ideas of all kinds—never before have so many manufacturers, and other patent buyers, been anxious to give good prices protected by O\'CONNER PATENTS. There is, today, a market for thousands of ideas—including YOURS. Write for more information and make yourself the hundreds of requests recently received.

You incur no obligation by writing me. My advice costs nothing and I make no charge, for an opinion as to patentability of your idea. If my opinion is favorable I will back it up by a Guarantee Contract which protects you fully. If you want to sell your invention, I will help you, and will advertise it, free of charge, in "INVENTION AND MANUFACTURING," a monthly magazine which will bring you at once, my four free books—"SUCCESSFUL PATENTS," a 72 page guide telling how to proceed, gives references, etc.; "STEPPING STONES" tells the truth about prizes for inventions, gives hundreds of hints of inventions wanted, etc.; "PAYMENT PATENTS," publishes over 400 requests of manufacturers and others who want O\'CONNER PATENTS, together with your ideas. Their "PAYMENT PROMOTION," tells you how to sell, why some inventors fail, discusses the value of your idea, etc.

Write for these books to-day. I will send you a signed agreement that will protect you before you disclose your invention.

RICHARD B. O\'CONNER, Patent Lawyer

OBTAINING ASSISTANCE FOR INVENTORS—Our certificate is of great assistance to inventors who require financial aid to obtain patents

OUR FIVE BOOKS MAILED FREE
(Save Copys Everywhere)

to any address. Send for these books—the finest publications ever issued for free distribution.

HOW TO OBTAIN A PATENT
Our illustrated book "Patents and Patent Claims" is a Book of Reference for Inventors and contains 100 Mechanical Movements, Illustrated and Described. Tells how to invent for profit.

WHAT TO INVENT
Contains information and suggestions concerning profitable fields of invention; also catalogues and registers offers for inventions amounting to ONE MILLION DOLLARS.

FRENCH LIST OF PATENT BUYERS
Contains requests from manufacturers, mail order houses and promoters of foreign patents. A Book of Reference for Inventors who wish to purchase. We plate our clients in touch with remittable free of charge. We have recently received over 500 requests from manufacturers.

AMERICAN LIST OF PATENT BUYERS
Contains requests from manufacturers, mail order houses and promoters of foreign patents. A Book of Reference for Inventors and will be of use to inventors who wish to purchase. We plate our clients in touch with remittable free of charge. We have recently received over 500 requests from manufacturers.

WANTED NEW IDEAS

FREE COUPON!
VICTOR J. EVANS & CO.
Philadelphia: 820 North Broad St.
New York: 333 Madison Ave.

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.
Our correspondent believes that such a ring would combine the advantages of both eccentric and concentric rings without their disadvantages, and at the same time possess the much desired leak-proof feature. Our advice is asked as to the patentability and practicability of this device.

A. The sketch which we reproduce herewith shows the idea clearly. The feature seems to be a particularly happy one, and to our mind it is a new idea which seems to us patentable.

On account of the wedge shape the ring will certainly prove non-leakable. We would, however, suggest trying out the idea in practice beforehand.

**Flashlight Battery.**

(242) T. Robertson, Havre, Mont., wishes to know if any patents have been granted on flashlights having storage batteries incorporated in same. Also if they are of the wet or dry cell type.

A. There is nothing new about this flashlight battery business, but the German manufacturers as well as in France and in England by certain flashlight makers, have what are termed batteries incorporated in the usual dry cell device. Cells of this kind are usually sealed, and are compactly arranged in a small case, to make a rule contain either powdered glass, glass wool, or other electrolyte of the gelatious kind to make the liquid immovable.

**Screwdriver.**

(243) Andrew M. Boehmich, Cleveland, Ohio, submits description and illustration of a non-screwdriver, the handiest and most perfect method of die castings. An arrangement is provided so as to lock the screw driver by means of a large nut. This A. is a very good idea and very clever, but we are afraid the screwdriver will be too expensive to manufacture and of course there is always a good demand for the better class screwdrivers of this kind. We think a patent may be obtained upon the device.

**A NEW ELECTRIC RECORDING COMPASS.**

(Continued from page 203)

Another seemingly fatal disadvantage one may think of at the outset is that the spark used on the compass would send out electric waves which will interfere with the ship's wireless receiving set. That this is not the case has been demonstrated and from theoretical considerations it is apparent that an undamped electric oscillation of such short wave length, and being practically surrounded by metal, as shown in this invention, will have no effect on the wireless equipment.

Today, after a year's ceaseless toil and disappointments, the electric recording compass bids fair to become an indispensable accessory of every ship. With the ever increasing installation of recording instruments of all kinds, instantly on the alert to detect any shortcomings on the part of the machinery or crew, the recording compass has been looked upon as an essential part of the equipment. Of what value is it to know, for instance, that the boiler pressure has been kept below the customary mark, that the steam engines have been functioning at the maximum efficiency, etc., when it is not known that the course has been properly maintained and that the passengers and cargo have not received that delicate care so requisite for their safety? All pilots are required to pass stringent and exacting examinations and have kept themselves informed of the latest developments, but in spite of this we always lack the irrevocable proof that he has steadfastly done his duty. The recording compass puts the seal of excellence upon his work if it is good—the stamp of reproach it be bad.

Today, aside from its other valuable features it is a marvelous stride in the advance of human progress as a safeguard to life and property.

**Patents, Make Your Ideas Pay**

Hundreds of Inventions are sold yearly. You may have yours without cost. Send sketch for free estimate, book and suggestions sent on request. Prompt service. Best results.

A. M. COLEMAN & COMPANY.

203 2nd National Bank Bldg., WASHINGTON, D. C.

**Electricians**

We sell you the motor complete or furnish you with the finished parts from which you can build as many units as you desire with few tools. We send you the printed instructions with prices quoted of the designs for $.25 or full particulars for 3-cent stamp.

ELECTRICAL EXPERIMENTER

ELECTRIC OR STEAM RAILROADS—WHICH?

(Continued from page 153)

8% efficiency. Now consider that during cold weather this same machine often loses 40% of its efficiency, due to the heat utilized in raising the temperature of the fuel. At 85°F, then, the heat units are required per lb. of water to raise steam.

Thus it is seen that in 20°F. cold weather, 232 - 127, or 105 more heat units, are required per lb. of water to raise steam; or 105 - 232 = 45% loss in cold weather. The mercury falls to -40°F. and more, the steam locomotives use so much heat from their coal to heat the water from the low temperature that they often freeze up, as pointed out in the official reports of the C. M. & St. Paul Railway and other systems.

Some very vital and illuminating statistics are cited in respect to the efficiency, or rather inefficiency of operation of steam railroads, in the address of President E. W. Rice, delivered before the American Institute of Electrical Engineers mid-winter convention.

Among other things, Mr. Rice said: “Where electricity has been substituted for steam, the efficiency has increased 35 to 40% because of the 3% to 5% increase in the available capacity of existing tracks and other facilities has been demonstrated.

Electric locomotives have permitted a saving in time of at least 50% and a cost reduction by some 25% under average conditions. In cold weather the electric locomotive actually has its hauling time reduced by three times. Water is a necessity for the steam locomotive is using up all its energy by heat radiation from its boiler (in cold weather) and engine into the atmosphere. By the use of electricity practically no useful power is available to move the train, the electric locomotive is operating under its most efficient conditions and may even work at a greater speed than the steam locomotive. But this is by no means all. The railroads of the country consumed 150,000,000 tons of coal in the year 1917. Electricity of the railroads would save at least two-thirds, or 66 2/3% of this, or coal; or electric locomotives substituted for steam types would save about half the tons of coal used in one year. This is an amount three times as large as the total coal exported from the United States during 1917.”

Further information by Government experts shows that the railroads of the United States used in 1915 twenty-four million five-horse-power of coal to haul forty million five-horse-power of total coal output to run their trains. Think of it! And again—electric haulage, as demonstrated by actual results obtained on the St. Paul, the Pennsylvania, and the Northern & Western, could have saved two-thirds of this, or 100,000,000 tons of coal, equal to five times the total amount used by all the electric central stations of the country.

Public announcement was recently made by Sir Robert Beck, London, Ontario, that the Canadian Pacific Railway, Canada’s premier transcontinental system, and one of the world’s greatest, is moving toward electrification of its entire system. Chairman of the Hydro-Electric Power Commission of Ontario, told the Board of Trade he was in a position to announce that the Canadian Pacific Railway was in a position to announce the cost figures on the cost of electrifying the Ontario lines, for estimate on the cost of electrification, for an indication of the possibilities of securing a supply of power from the publicly owned hydro-electric system. He further stated that the Canadian Pacific Railway has been in a position to take some time with the electrical operation of Chicago, Milwaukee & St. Paul Railway. The coal famine in Canada and steam inefficiency in the rigorous winters, it is reported, has directed the attention of the Canadian Pacific Railway to electric traction.

On one of the Southern coal roads, with long hauls to reach the consumer, nearly 25 per cent. of the coal output is used on the locomotives which haul the coal to market, according to Mr. Rice. Did you ever stop to think that practically all of this 150,000,000 tons of coal consumed by the railroads has to be hauled up from the mine to various section terminals along the line, sometimes a thousand miles or more. And again, that a considerable amount of the mercury is spilled back again in the locomotive tender. Mr. Rice, Jr. in his paper cited above, stated in this connection: “It is estimated that fully 16 per cent of the total ton-mileage movement behind the engine draw-bar is made up of company coal and coal cars; including in this connection the steam engine tender and its contents. There is available in the United States 25,000,000 H.P. of water power; if this were developed and could be used in the fashion of the steam locomotive, every horsepower so used would save at least 6 pounds of coal per horse-power hour now burned under the boilers of our steam locomotives.

Water is one of the most valuable quantities by all steam locomotives, of course—millions of gallons of it annually. The illustration herewith serves to show how the water is pumped by the steam locomotive and piped or purchased, as in cities, and distributed all along the line at intervals of 20 to 30 miles.

Based on the fact that the 65,000 steam locomotives in the country operated about half the time, or, let us say, half a year, then they would consume the rainwater, of which there is over 20 trillion gallons a year. This total amount is equal to six months’ water, or 24 million five-horse-power of coal needed to heat it.

The two illustrations herewith show the latest high-power electric and steam locomotives compared with their present horse-power ratings and losses along the systems on which they operate. The engines are about equal in size and strength and give a clear idea of their relative efficiency. As already mentioned, the steam engine realizes about 7% gross efficiency, whereas it is stated that the electric locomotive, as shown, developing 4,000 H.P., shows a gross efficiency of 89%. This means but little in a way; rather, it is the over-all efficiency of the entire system that really tells the tale. Here are the facts:

Efficiency of Electrically-Railroaded

With hydro-electric power (ordinarily without regenerative braking), gross efficiency from water power to locomotive = 36%. In the case of the C. M. & St. Paul R. R., the engines deliver power back to the system when coasting down mountains to the amount of 15%. Hence the gross or over-all efficiency here equals 71%.

With mouth-of-mine centralized electric generating, stations, gross efficiency from coal burned to electricity delivered to locomotives = 10 to 12 per cent. This eliminates coal mining and haulage, reducing the labor required incidentally.

With "natural gas" engine plants, gross efficiency from gas used to electrical energy delivered to locomotives = 24 to 30%. With the "gas producer" plants operating on coal at mouth of mine, the gross efficiency from coal burned to electrical energy delivered to the locomotives = 24 to 28%.

Present Steam Railroad Efficiency.

With coal-burning locomotives, gross efficiency

is shown at C. This arrangement may comprise a permanent steel magnet, X, with an electro-magnet, Y, secured at the center. The diafragram is then acted upon in this case at the center, and electrically in both sides. Some single-pole receivers utilize a permanent magnet punching similar to that illustrated at D. In this case the magnetic flux from the single-pole type of receiver has returned thru the air, thus encountering considerable reluctance (magnetic resistance) of course, and these receivers are therefore not as efficient as the double-pole type, as the magnetic reluctance of air is several hundred times greater than it is for iron or steel. At E, F, a typical pole-piece from a bipolar watch-case receiver is illustrated, where 1 and 2 are the fiber end-checks which are slotted over the pole-piece preparatory to winding the coil on it. The face of the pole-piece which is next to the diafragram is swaged over as shown to hold the coil check in place. It is common practice to provide several narrow slots as shown in the drawings, these slots extending from the face of the pole-piece to the bottom of the frame. Several of the best makes of wireless 'phones have these slotted pole-pieces, which tend to reduce the losses due to Eddy currents, which are produced in the space of the pole of any receiver whenever the diafragram moves and represent a loss in efficiency, develop heat, etc. All of the best grades of wireless 'phones are provided with some form of protective spark-gap or other device as shown at Fig. 2-F to prevent heavy static or other surges from burning out the windings in the receiver. A very small condenser is sometimes connected across the binding-post terminals of the receiver or else a high resistance. If a spark-gap is used for the apparatus, it should be of the microimeter type provided with threaded electrode screws so that it can be adjusted very closely, the gap not being over .01 inch in length.

Fig. 3 illustrates a vibrating reed radio receiver patented by S. G. Brown in England. This receiver is of the watch-case type having a shell, A, and an ear-piece or cap, B. The vibrating member comprises a thin reed, C, attached, several, of the best makes of wireless 'phones have these slotted pole-pieces, which tend to reduce the losses due to Eddy currents, which are produced in the space of the pole of any receiver whenever the diafragram moves and represent a loss in efficiency, develop heat, etc. All of the best grades of wireless 'phones are provided with some form of protective spark-gap or other device as shown at Fig. 2-F to prevent heavy static or other surges from burning out the windings in the receiver. A very small condenser is sometimes connected across the binding-post terminals of the receiver or else a high resistance. If a spark-gap is used for the apparatus, it should be of the microimeter type provided with threaded electrode screws so that it can be adjusted very closely, the gap not being over .01 inch in length.

L. J. LEISHMAN COMPANY
Dept. T, Ogden, Utah

---

The condenser or electro-static receiver, as it is more commonly known, is based upon the fact that a condenser can reproduce speech when connected to a suitable circuit. The Clarke—Churchill condenser receiver was first successfully applied by Prof. Dollbear. Elisha Gray, in 1865, found it possible to use with the d'Arsonval, and he also at that time described a form of musical telephone receiver based upon electro-static attraction.

Fig. 1 shows the improved form of electro-static telephone receiver. This receiver is provided with a sound-conducting tube and ear-piece, and at its base carries a sound-sensitivity wave-meter, as shown in the drawing. In this particular design India rubber was found best for the condenser leaves, the distributing properties and low dielectric losses of the aluminum shell is provided as shown, which has an opening at the top and over which the alternating rubber and soft iron leaves are stretched. These rubber and foil leaves are firmly secured around the peripheral to prevent any irregular vibration. Each rubber leaf is about .4 mm. thick. The sound-reflecting plate at the base of the receiver serves to reflect any sounds emanating from the inner surface of the flexible shell plates for the condenser are composed of aluminum leaf about .001 mm. thick, these aluminum leaves being secured to the rubber leaves by a spring-like flexible bar. When the volume of receiver was tried with two hundred and forty volts, it was found that the volume was equal to that of an electro-magnetic loud-sounding receiver, and that volume increased substantially with three hundred and four hundred volts, respectively. One or other of the electro-static telephone receivers made and tested by Messrs. Orr & Rieger had a capacity of .008 m.f.

Several investigators have endeavored to reproduce a magnetic circuit of a direct type of telephone involving the heating and cooling of a fine electrical conductor. This principle is utilized in the telephone shown in Fig. 6. This telephone has the simplest form of telephone receiver ever designed, and of recent years has been quite successfully developed in Europe, notably by Mr. DeLange. The receiver consists merely of a small tube provided with an opening, the tube being small enough to be inserted into the ear. The armature member comprises a short loop of strip Wollaston wire secured to two heavy wire leads in the manner indicated. In practice the Wollaston wire is inserted in the aural passage: any sudden heating of this fine wire by a small current causes a sufficient and very marked vibration which in turn affects the ear drum. It has been found advantageous in some cases to have a small current passing permanently thru the loop.

The electro-dynamic receiver is illustrated in Fig. 7. This is also known as a dynamometer receiver. It is designed by Prof. G. W. Pierce for use with his type of wave-meter. This receiver is not as sensitive as the regular type, but for certain purposes has certain advantages, one of them being that it can be connected directly in series with the condenser and exploring inductance of a wave-meter (provided it is connected with the wave-meter, thus allowing for the inductance of the winding in the receiver) as in Fig. 8, in which case it will indicate the resonance point by giving a maximum strength of signal, the same as when a detector and a pair of parallel condensers are connected in series. The construction of the dynamometer telephone is very simple, comprising as it does, a hard rubber or other insulating bobbin on which the magnetic coils are wound and the resistive part of seventy-five to one hundred and fifty ohms, and in front of this there is placed a light copper or silver diaphragm. No iron is used in the receiver, and its action is based upon the fact that attraction is set up between the current in the armature winding and the magnetic poles of the receiver, or copper diaphragm. As Shepard points out, even the diaphragm may be omitted, the minute movements of a loosely wound coil being sufficient to reproduce speech or signals.

The Baldwin amplifying receiver is one of the best direct wave-meters. As before receiving instruments and possesses a remarkable sensitivity. Its sponsors state that this receiver will amplify the incoming signal so as to be heard distinctly. A considerable number of tests were made at the Radio Laboratory of the College of the City of New York, by Mr. T. T. flyer,with particular receiver and showed very superior results. As shown in the illustration, it comprises a permanent steel magnet which is furnished with soft iron poles and a coil shaped as indicated, and between which there is placed the electro-magnetic winding of high resistance, also a light, balanced, soft iron armature pivoted at the center. One end of this armature is connected by a brass wire or link to a mica or insulating tube. The soft iron armature is of normal size, akin to those not familiar with this particular instrument such might not seem the case off-hand. When, however, an alternating current is produced in the telephone winding, the soft iron armature is caused to vibrate, and these vibrations are transferred to the diaphragm by the link already mentioned. As becomes evident, this receiver is unlike all other electro-magnetic receivers, in that the iron armature and the coil are in such a manner that an incoming current passes thru the winding. This is so, owing to the fact that the flux from the permanent magnet divides equally between the magnet coil, the soft iron poles and continues thru the magnets. Owing to this division of the magnetic flux, there is therefore no constant magnetic field, as in the case of the common telephone receiver, as we learned in the forepart of this article. The superior sensitivity of this receiver is due to several reasons, among which are the following: the magnetic circuit has a very low reluctance, and also the armature of the receiver is used as a wave-meter, the current passing thru the winding, thus yielding a greater deflection of the diaphragm, and again the armature is acted upon by all the field and not by the conductor alone. By this means, the deflection of the wave-meter is proportionally increased.

Fig. 9 shows a type of radio receiver developed several years ago, in which the pole-pieces are made adjustable by virtue of a small thumb-screw protruding thru the back of the shell. As aforementioned, this type of 'phone permits the operator to control or regulate the strength of the signal, or also when temperature changes may cause the diaphragm to sag and touch the pole-pieces; for strong signals this receiver can thus increase the length of the air gap, and for weak signals he can advance the pole-pieces until they almost touch the diaphragm.

Another excellent type of adjustable air gap radio receiver is shown at Fig. 10. This receiver is known as the R.F. Mead, and is so arranged that the diaphragm is being rigidly locked in the adjustable cap, so that whenever the cap is turned on the shell, the diaphragm will be forced to ride in the air gap, regardless of the magnetic pole-pieces. The diaphragm is locked in the cap by means of a threaded ring. This phone has a graduated scale of galvanometer readings, and the indicator is mounted or engraved on the edge of the movable cap. Thus when an opera-

How I Improved My Memory In One Evening

The Amazing Experience of Victor Jones

“Of course I place you! Mr. Addison Sims of Seattle.

“If I remember correctly—and I do remember correctly—Mr. Burroughs, the lumberman, introduced me to you at the luncheon of the Seattle Rotary Club three years ago in May. This is a pleasure indeed! I haven’t laid eyes on you since that day. How is the grain business? And how did that amalgamation work out?”

The assurance of this speaker—in the crowded corridor of the Hotel McAlpin—compelled me to turn and look at him, though I must say it is not my usual habit to “listen in” even in a hotel lobby.

“He is David M. Roth, the most famous memory expert in the United States,” said my friend Kennedy, answering my question before I could get it out. “He will show you a more wonderful things than that, before the evening is over.”

And he did.

As we went into the banquet room the toastmaster was introducing a long line of the guests to Mr. Roth. I got in line and when it came my turn, Mr. Roth asked, “What are your initials, Mr. Jones, and your business connection and telephone number?” Why he asked this, I learned later. I was picked out from the crowd the 60 men he had met two hours before and called each by name without a mistake. What is more, he named each man’s business and telephone number, for good measure.

I won’t tell you all the other amazing things this man did except to tell how he called back, without a minute’s hesitation, long lists of numbers, bank clearings, prices, lot numbers, parcel post rates and anything else the guests gave him in rapid order.

**********

When I met Mr. Roth again—which you may be sure I did the first chance I got—he rather bowled me over by saying, in his quiet, modest way:

“There is nothing miraculous about my remembering anything I want to remember, whether it be names, faces, figures, facts or something I have read in a magazine.

“You can do this just as easily as I do. Anyone with an average mind can learn quickly to do exactly the same thing which seem so miraculous when I do them.

“My own memory,” continued Mr. Roth, “was originally very faulty. Yes it was a really poor memory. On meeting a man I would lose his name in thirty seconds, while now there are probably 10,000 men and women in the United States, many of whom I have met but once, whose names I can instantly on meeting them.”

“That is all right for you, Mr. Roth,” I interrupted, “you have given years to it. But I can’t do it.”

“Mr. Jones,” he replied, “I can teach you the secret of a good memory in one evening. This is not a guess, because I have done it with thousands of pupils. In the first of seven simple lessons which I have prepared for home study, I show you the basic principle of my whole system and you will find it—not hard work as you might fear—but just like playing a fascinating game; I will prove it to you.”

He didn’t have to prove it. His Course did: I got it very soon after his publishers, The Independent Corporation. When I tackled the first lesson, I suppose I was the least remarkable man in forty-eight states to find that I had learned—in about one hour—how to remember a list of one hundred names so that I could call them off forward and back without a single mistake.

That first lesson stuck. And so did the other six.

Read this letter from C. Louis Allen, who at 52 years is president of a million dollar corporation, the Nile Manufacturing Company of New York, makers of the famous fire extinguisher:

“Now that the Roth Memory Course is finished, I want to tell you how much I have enjoyed the study of this most fascinating subject. Usually courses involve a great deal of drudgery, but this has been nothing but pure pleasure all the way through. I have derived much benefit from taking the course of instructions and feel that I shall continue to strengthen my memory, which is the best part of it. I shall be glad of an opportunity to recommend your work to my friends.”

Mr. Allen didn’t put it a bit too strong.

The Roth Course is priceless. I can absolutely recommend it now, and I can tell you the name of most any man I have met before—and I am getting better all the time. I can remember any figures I wish to remember. Telephone numbers come to mind instantly, once I have filed them by Mr. Roth’s easy method. Street addresses are just as easy.

The old fear of forgetting (you know what that is) has vanished. I used to be “scared stiff” by my feet—but I wasn’t sure. I couldn’t remember what I wanted to say.

Now I am sure of myself, and confident, and “easy as an old shoe” when I go on my feet at the club, or at a banquet, or in a business meeting, or in any social gathering.

Perhaps the most enjoyable part of it is that I have become a good conversationist—and I used to be as silent as a sphinx when I got into a crowd of people who knew things.

Now I can call up like a flash of lightning most any fact I want right at the instant I want, and I think that a ‘hair trigger’ memory belonged only to the prodigy and genius. Now I see that every man of us has that kind of a memory if he only knows how to make it work right.

I tell you it is a wonderful thing, after grooping around in the dark for so many years to be able to switch the big searchlight on your memory. To see instantly everything you want to remember. This Roth Course will do wonders in your office.

Since we took it up you never hear any one in our office say ‘I guess’ or ‘I think it was about so much’ or ‘I forget that right now’ or ‘I can’t remember’ or ‘I just look up his name.’ Now they are right there with the answer—like a shot.

Have you ever heard of ‘Multigraph’ Smith’s? Real name H. Q. Smith, Division Manager of the Multigraph Sales Company, Ltd., in Montreal. Here is just a bit from a letter of his that I saw last week:

“Here is the whole thing in a nutshell: Mr. Roth has a most remarkable Memory Course. It is simple, and easy as falling off a log. Yet with one hour a day of practice, anyone—I don’t care who he is—can improve his Memory 100% in a week and 150% in six months.”

My advice to you is don’t wait another minute. Send to Independent Corporation for Mr. Roth’s amazing course and see what a wonderful memory you have got. Your dividends in increased earning power will be enormous.

VICTOR JONES

Send No Money

So confident is the Independent Corporation, the publishers of the Roth Memory Course, that once you have an opportunity to see in your own home how easy it is to double, yes, triple your memory power in a few short hours, they are willing to send the course on free examination.

Don’t send any money. Merely mail the coupon or write a letter and the complete course will be sent, all charges prepaid, at once. If you are not entirely satisfied send it back any time within five days after you receive it, and you owe nothing.

On the other hand, if you are as pleased as are the thousands of other men and women who have used the course send only $5 in full payment. You take no risk and you have everything to gain, so mail the coupon now before this remarkable offer is withdrawn.

FREE EXAMINATION COUPON

Independent Corporation
Division of Business Education, 119 West 40th St., New York
Publishers of The Independent and Harper’s Weekly

Please send me the Roth Memory Course of seven lessons. I will either remit the course to you within five days after its receipt or send you $5.

TELEGRAPH

TELEGRAPH—Both MORSE and WIRELESS: STATION AGENCY, taught quickly, TREMENDOUS DEMAND—greater than supply. NEW DEGREES SECURED—HIGHER SALARIES. IDEAL WORKING CONDITIONS. GREAT OPPORTUNITIES FOR ADVANCE- MEN. WOMEN OPERATORS also needed. All expenses provided. First-class accommodations. Oldest and largest school—established 44 years. Endorsed by Railway, Western Union and Marenol officials. Now offering special three months' radio course for young men subject to draft, enabling them to enter the FEDERAL TELEGRAPH SERVICE.” Large illustrated catalogue free. Correspondence course also. WIRE ENROLL IMMEDIATELY. DODGE'S INSTITUTE, Lone St., Valparaiso, Indiana.

TRICKS, PUZZLES AND GAMES

1000 Stage Tricks with 500 illustrations. 20¢, Small Catalog FREE. Hurlock Magic Co., Sta., 60780 Eighth Ave, New York.

DECAMPO—Easy secret system reading back, $1.50. Stovers', Enola, Pa.

WANTED

EXPERT WATCH REPAIRING. Reduced Prices. References. Leo Hirsh, Elkhart, Ind.

PRINTING

FOR ADVERTISERS

"QUICK-ACTION ADVERTISING—How it is Building Business for the Progressive Advertiser," published by the advertisers themselves—not the publisher. You will be interested in reading this little booklet which contains some interesting and responsive testimonial letters from every newspaper to whom you have mailed our book, a copy of which will be gladly mailed to you upon request. It tells how 1,000,000 intelligent, interested and responsive advertisers are using every method and every device to get the business they want and who have the money to buy it. Write for particulars. Offices are in the Walth- field Courtyard, 223 West 29th St., New York.

INSTRUCTION

DETECTIVES make big money! Travel and live in style! Free instruction to you at a nominal cost. Write for booklets. American School of Criminology, Dept. A, Detroit, Mich.

MISCELLANEOUS

TOBACCO or Snuff Habit cured or no pay. 5¢ if cured. Request sent on trial. Superbo Co., SA, Baltimore, Md.

WANTED—E. Kety, D. D. S., M. D., pyrotherapist specialist for 15 years, has developed a successful home treatment for pyorrhoea. Purify; drain; cure $5.00. Write today. Free booklet and booklet $1. Circular free, Dr. H. E. Kety, 22 Prospect Place, Brooklyn, N. Y.

BROTHER—Tobacco is foolish, injurious, expensive habit. Quit easily with Nature’s pleasant substitute. I’ll gladly send necessary particulars. Wallace Stokes, Moksha, Florida.

WE HAVE completed beautiful of artistic pictures on hand of Nikola Tesla and Dr. Lee De Forest. These make a handsome decoration for your laboratory or study. Send 10¢ and they will be prominently displayed. Price for both, prepaid, 10¢. Experiment-Fab. Co., 233 Fulton St., New York.

"OPPORTUNITY AD-LETS" bring quick results. For 100,000 copy, you are making money—so can you. For proof ad- classes Classified, 50¢, electrical experimen- ter, 233 Fulton St., New York City.

OBER 1,000 NET PAID CIRCULATION GUARANTEED, A. B. C. AUDIT

FOR SALE—Complete Wireless Set, including aerials, 41 v, 6-volt Dynamo, $125; Rex Motor, 65c; Sounder, $1.25; Key, 65c; Telephone Generator, transmitters, bells; wire, etc. Further information on request. Wm. Harmeling, Zeeland, Mich.

WANTED—3 to 4 HP. Simplex motor, 110 volts, 3 ph. Runs small and quiet. Have electric circuits, etc. 146 Riverside, New York.

WANTED—(Sealey) Inductive motor, motors run small, 1, 2, 3, 4, 6, 8, 10, 15 in. K. W. transformer. Complete outfit for Lecture work. Dr. A. A. Chisholm, 6 Main St., Chippawa, N. Y.

BARGAIN—Five-dial Omnigraph, $5. Also $4 box camera, $2 Walter Parker, 247 Bedford St., Cumbertun, N. Y.

329 Elm St., Penn Yan, N. Y.

Gentlemen:

I wish to tell you of the successful results I obtained from my ad in the "E. E." They have been "pouring" in at the rate of several each day.

To date, I have received sixty-three inquiries and two actual demands for articles advertised.

Orders have come from as far South as Florida, West from Colorado and several foreign countries.

Thanking you for your promptness in inserting my ad, I remain,

Lester Chisholm.

FOR SALE—Complete Wireless Set, including aerials, 41 v, 6-volt Dynamo, $125; Rex Motor, 65c; Sounder, $1.25; Key, 65c; Telephone Generator, transmitters, bells, wire, etc. Further information on request. Wm. Harmeling, Zeeland, Mich.

WANTED—3 to 4 HP. Simplex motor, 110 volts, 3 ph. Runs small and quiet. Have electric circuits, etc. 146 Riverside, New York.

WANTED—Foot Power Lathe with chuck and tools. Owner, M. G. Meister, 29 Main St., Rochester, N. Y.

MOTORCYCLE WANTED—Will exchange printing press and complete outfit, wireless receiving and other equipment for motorcycle and dynamo, motorcycle engine and tank, good condition. What have you? John Burke, 17 Eil St., Valley Falls, 11.

FOR SALE—110 v. magneto generator, $275. Automobile Presto tank, $15; gasoline 100-air electric carriage lamp, $2; ball bearing steam tur- bin, $10. Emerson Kazy, Van Buren, Ohio.
Every Electrical Man Wants These Books and we ship them for your inspection FREE

Flexible Covers
Handy Pocket-Size Volumes

Just what you need to know to succeed in ELECTRICITY

EVERY electrician, every engineer, every mechanic should know about these wonderfully helpful instructive books, which give in plain words a complete working knowledge of electrical engineering in all its phases.

You run into some new electrical problem almost every day. The information you need to help you in your every day work is in HAWKIN'S ELECTRICAL GUIDES

These books place electricity at your finger ends. They cover every imaginable subject, principle, theory, problem, trouble, and way of doing things electrically. Every subject is indexed so that you can turn right to it. They are a study course and a reference guide in one, written to be understood by electricians in any language—no wasted words—only what you need to know—check full of up-to-the-minute electrical knowledge. The guides are a complete course in electrical engineering. They will help you in every detail of the day's work. You can't ask an electrical question that Hawkins Guides can't answer.

What Electrical Men Say

Helped Him Make Good

"It is rare for me to recommend highly the Hawkins Guides, for they have been the greatest assistance to me in placing me in my present position as a Superintendent of Construction Department of one of Ohio's largest Electrical Companies. I am trying to see every man have a set of Hawkins Guides."

Gen. Rinkert, Columbus, Ohio.

In the Naval Electric Dept.

"The Hawkins Guides are a great help to us in the Naval Electrical Department. It gave us greater understanding of the equipment and individual parts."

E. R. Receivng Ship, Brooklyn, N. Y.

Superintendent

"I am now superintendent of the Dunsmuir Hydro Electric System, and Hawkins Guides were a great help to me in holding down a responsible position.

W. E. Swift, Dunsmuir, Ontario.

Wireless Operators

"I have been a wireless for ten years—but I wish I had these books ten years ago, so I have saved up a great deal of trouble."—J. Marshall, Steamer M. V. "Wadsworth".

Pocket-Size Flexible Covers

The books are small enough to slip into your coat pocket—handily bound in flexible elastic covers. You can carry each volume with you until you have mastered its contents. 3,500 pages of actual information and 1,300 illustrations. Once you see these books and the first you will want to have the complete set, and then again want to be without them. Try it at our expense.

SEND NO MONEY

It will cost you nothing to receive these books—in both cases take them all the questions you can think of—but let them in your work—study them—pick up some information that will increase your earning ability. We will ship you the entire set of 10 volumes entirely FREE.

This is a save of our confidence in the guides. Paste gold does not object to being tested. Keep them for seven days and if you do not decide that you cannot get along without them, return them to us and owe us nothing.

The cost of a subscription to the guides. Past gold does not object to being tested. Keep them for seven days, and if you do not decide that you cannot get along without them, return them to us and owe us nothing. We decide to keep them only to pay $1.00 down and remit the balance of $0.00 on the easy payment of 25c a month. Use this coupon to get the books. It will pay you many times over.

READ THIS PARTIAL LIST OF CONTENTS

No. 1 Contains 314 pages, 254 illustrations. Electrical apparatus and symbols—magnetism—static and current electricity—primary cells—cathode rays and radioactivity—auxiliary resistances—conductivity—ionic—inductive circuits—velocity of electricity—static electricity—oscillations, etc.

No. 2 Contains 314 pages, 254 illustrations. Motor principles—armature reaction—motor starting—calculating—make interconnector—selection and installation of dynamo and motors—amperes—standard cells—current measurement—resistance measurement—volts—watt-hours—watt-hour meters—operating voltage—operation of dynamos—operation of motors, etc.

No. 3 Contains 200 pages, 124 illustrations. Distribution of work and underground wiring—sign—fuses—lighting protection—recycled—overcurrent—building construction, etc.

No. 4 Contains 174 pages, 379 illustrations. Alternating current—powertapping—alternating current distribution—wiring—conduits, etc.

No. 5 Contains 200 pages, 113 illustrations. A.C. Motors—synchronous and induction motor principles—C.C. motors—induction devices—transferrable loads, construction, connections, tests, controllers, testers, etc.

No. 6 Contains 254 pages, 172 illustrations. Alternating current systems—switchgear—power failures—alternating current—wiring by wire—telecomunication—devices—power factor indicators—wire form measurement—switch boards, etc.

No. 7 Contains 316 pages, 379 illustrations. Alternating current, wiring power stations—turbines—management, selection, location, erection, testing, running, care, repair, etc.

No. 8 Contains 312 pages, 458 illustrations. Telegraph system—electrical telegraphy—radio telegraphy—wireless—electricity for distributing—arrangement of lines, insulators and building systems, electric wiring, etc.

No. 9 Contains 332 pages, 327 illustrations. Electrical trade—electrical devices—electrical standards—wiring—steering—motoring—operating—motor vehicles—industrial electricity—high-voltage—electric motors, etc.

You benefit by mentioning the "Electrical Experimentor" when writing to advertisers.
We want ambitious men and women to have these remarkable Charts which are a visual demonstration of Chiropractic, the new science of Drugless Healing. This offer is now made to show the opportunities now open to Chiropractors. We also explain how we give a practical training by mail in this dignified, paying profession. If your desire is to enter an uncharted field—if you want to achieve financial independence and social standing, at least investigate. Your request on the coupon below is all that is necessary.

**Drugless Healing**

The 72-page book and other literature we send on request shows the immense possibilities for Chiropractors of both sexes. The public is awakening to the fact that drugging to cure disease is in many instances, a fallacy. They are ready to welcome the practitioner who relieves and heals without nauseous dosing. The Charts show how the science of Chiropractic is applied. They reveal facts about the human body, instructive to the layman. You should obtain them without fail.

**$3000 to $5000 a Year**

Many Doctors of Chiropractic earn $5,000 a year and more; some upwards of $10,000. Dr. M. D. Moore of Ky., reports an income of $9,000 a year. Dr. L. H. Roche, New Jersey, $5,500; Dr. Hanna of Florida, over $5,000 yearly. What others are doing you should be able to do. A diploma gives you the same opportunity—is evidence that you are master of a profession of dignity, prestige and influence.

**Our Lessons Teach You**

how to make Spinal Adjustments for speedy relief of

**Be a Chiropractor**

Learn At Home

By the American University system of instruction, you can become a Doctor of Chiropractic by studying in spare time at home or in class at the University. You do not require special talent or advanced education. A common school education and the ambition to succeed are all that is necessary. You will be trained under the direction of Chiropractic specialists who will teach you thoroughly the principles and practice of the profession. You will graduate with the degree of Doctor of Chiropractic.

**Mail the Coupon**

This coupon will bring full information about this new, interesting and profitable calling which any intelligent man or woman can readily master by our method—also information on how you can get these 22 instructive Charts. Send coupon for this free offer.

**AMERICAN UNIVERSITY**
Manierre Bldg., Dept. 252 Chicago, Illinois

Gentlemen: Without cost or obligation, send me by mail, your new, illustrated, 72-page book and your Free Charts Offer.
YOUNG MEN LISTEN

The country needs more trained, graduate electricians. Thousands have gone into the Government service and there is such an unusual demand for competent electrical men that I am making a wonderful offer at this time. HERE IS YOUR OPPORTUNITY! I want to send you my splendid offer now.

Don’t hesitate because of age or experience. Young men, boys and old men must now fill the gaps and keep business going. DO YOUR PART. Prepare yourself for a real position by my Home Study Course in Practical Electricity. I am Chief Engineer of the Chicago Engineering Works. I have trained thousands of men and can help you better than anybody else. We also have large, splendidly-equipped shops where you can come at any time for special instruction without charge. No other correspondence school can give you this.

SPECIAL OFFER: Right now I am giving a big, valuable surprise that I cannot explain here, to every student who answers this ad. Write today!

$46.00 to $100.00 a Week

Go after some real money. Qualify for one of the thousands of splendid positions open. All you need to start is a few months snappy, practical instruction from a competent engineer. Come to me—NOW. I’ll give you my personal care to ensure rapid and efficient progress. My course is intensely practical. It is highly condensed, simplified, up-to-date and complete. I am so sure you will make a splendid success in this study, that I will Guarantee Under Bond to return to you every cent paid for tuition, if you are not entirely satisfied when you receive your Electrician’s Certificate granted you as a graduate of my school.

FREE—Lessons and Outfit—FREE

Send me the Free Outfit Coupon at once. Do it now! For a limited period I am making a slashing cut in the cost of tuition, and giving each new student a grand outfit of Electrical Tools, Material and Instruments—in addition—Absolutely Free. I will also send you—free and fully prepaid—Proof Lessons to show you how easily you can be trained at home to enter this great profession, by means of my new, revised and original system of mail instruction.

ACT PROMPTLY

Get the full benefit of this great offer. Send the Coupon or a postal for free information without delay. Do it now—before my free offers and guarantee are withdrawn.

Feldman “Geyser” Electric Water Heater

INSTANTLY

The Hot Bath Is Ready

Continuous Flow of Water as Desired. Always Ready

You only pay for electricity as used. All water that passes through the heater is thoroughly sterilized. The Feldman “Geyser” is perfectly insulated and is absolutely safe, no danger of short circuiting or electric shock.

Cold to Hot Water by Merely Turning Handle

Both the water and the current act together and both controlled by the movement of the faucet handle. To secure hot water turn handle to the left, for cold water turn to the right, at the center both the water and current are shut off.

The Supreme Court has decided that we control the absolute right to the manufacturing of Feldman “Geyser” Electric Water Heater. Others take warning, as we will prosecute any infringing on same. Write us today to send you full information.

Our new, special 110 volt electric water heater will also soon be ready and on the market. Will be ideal for use where connection to ordinary socket on regular lighting system is desired. Requires no extra wiring. WATCH FOR IT.

You benefit by mentioning the “Electrical Experimenter” when writing to advertisers.
EXPERIMENTER'S! ATTENTION!!

"ELECTRO" LOUD-TALKER

We present herewith two little instruments for which we have had a long and persistent demand.

This outfit has been gotten up solely for the Experimenter and for this reason we are selling it "Knocked Down." This telegraph words, the instruments come all ready for you to assemble, all the parts, screws, nuts, washers, etc., being furnished. Complete directions how to assemble accompany each set. With a pair of pliers and a screw-driver, the outfit can be readily put together in less than twenty minutes.

The most important point is that the telephone receiver spool comes already wound complete, to lead the Experimenter will, therefore, not need to wind his own spool.

The outfit when assembled comprises a highly sensitive CARBON GRAIN MICROPHONE with carbon diaphragm of exactly the same type as is used with our $15.00 Detectophone. (See our Cat. No. 19.)

The receiver is a special low resistance double pole type with the difference that no magnet is used in the same for the reason that the function of this instrument is electro-magnetic, the same as all loud-talking phones.

The spool is wound with special enamel wire for five ohms, standard with our Detectophone. This instrument works best on four dry cells, and particular attention is called to the fact that in order to work, the loud-talker requires a fairly heavy current and for that reason thick wires must be used for connecting the transmitter with the loud-talker. If this is not done, the voice will be weakened considerably. If no heavy wire is at hand, more batteries must be used to compensate.

USES: This Instrument can be used to transmit phonograph music from one room to another; used as a Detectophone; as a Radio Amplifier; as a telephone extension (by placing the regular telephone receiver against the sensitive transmitter with the loud-talker); for salesmen to talk "through" window (Loud-Talker outside in street, microphone Transmitter for salesmen, talking into same); for restaurants for taking the check, and a hundred other uses. Many young experimenters are developing a lucrative business selling this appliance to various merchants at a profit.

Outside of the two instrument parts, one three-foot cord is furnished with sensitive microphone as shown; instructions, etc., are furnished.

No. AEK205 "Electro" Loud-Talker Outfit Parts, "Knocked Down," complete...........................
No. CER205 "Electro" Loud-Talker Outfit, same as above except that it is already assembled and tested at factory. Set complete...........................

Shipping weight 2 lbs.

S. O. S.!! A REAL ELECTRIC

Learner's Telegraph Outfit for 25c Prepaid

In the 15 years of its existence our company has never offered such a bargain as the present one. Just think of it, a real electric learner's telegraph outfit with which to learn the code or to telegraph to your friend six blocks away, for 25 cts.!! Impossible—you say. Quite so. We do sell them at cost, but we do it solely to get you acquainted with us and place our wonderful catalog in your hands. And if this telegraph pleases, you will order other things from us. This telegraph has a red-lacquered wooden base, strong electromagnet, nickel binding posts, generous telegraph knob, and nickel clicker. Telegraph measures 3½ x 1½ x 1½ over all. Full directions for learning the code, and a fine CODE CHART go with the telegraph, all packed in neat box. Telegraph works easily on a single dry cell. Two instruments may be ordered for 50 cts., if wanted, to telegraph between two rooms or two houses.

"THE LIVEST CATALOG IN AMERICA"

Our big, new electrical cyclopedia No. 19 is waiting for you. Positively the most complete Wireless and electrical catalog to print today. 250 pages, 600 illustrations, 500 instruments and accessories, etc., etc. Wireless Telegraphy and Phone. "ENJOY" a free copy. FREE Cyclopedia No. 19 measures 7½ x 9½. Weight 9 lbs. Beautiful stuff covers.

"THE LIVEST CATALOG IN AMERICA"

Now before you turn this page write your name and address on coupon at left, cut or tear out, enclose 5 cts. stamps to cover mail charges, and the Cyclopedia is yours by return mail.

AN ELECTRIC CHICK PICKER, by H. Gernsback. 240

HOMER'S Iliad tells us how the Greeks, the beleaguerers of Troy for over ten years, were unable to take the city, nor could they force the Trojans to surrender. Finally, so the legend goes, the Greeks constructed a huge wooden horse, which in its interior was filled with Greek warriors. This horse was rolled triumphantly into Troy by the Trojans, but during the night the Greek men escaped from the horse and threw open the passageway to the city. The Greek hosts having returned now swarmed into the city and sacked Troy. This was over two thousand years ago. Legends such as these, it seems, were just as popular then as they are now, at any rate the longing in the human breast for the spectacular during wartimes seems hard to eradicate.

It is only natural that war weary people should be fond of giving their imagination free reign and of hoping that by some miracle a wonderful invention will suddenly appear which will end the war with one stroke.

Unfortunately, history, with hardly any exceptions, teaches that but few wars were won by means of any one war invention. Wars in recent times from Napoleon down to this war have not been won by means of any particular invention. Napoleon did not surrender on account of a war weapon that was known only to his connoisseurs. Nor were the American Civil War, the Franco-Prussian War, nor the Russo-Japanese War won or lost by a new war machine.

If this is true of all other great wars, how much truer is it of the present cataclysm. Unheard and undreamed of inventions, that would have staggered human-ity twenty years ago, have been thrown into this inferno, and to what good? The bombing aeroplane, the submarine, wireless, telephones, heavy gas, the water tank, liquid fire, the 75 mile gun, are all first class war inventions, every one of which would have spelled victory to Napoleon, had he possessed the secret. And wonderful as every one of these inventions is, none of them alone have been able to bring about a decision.

Nor are they likely to do so. The Germans thought the submarine would bring a decision, their experts staking almost their last card upon it. It has been a ghastly failure, otherwise how could a million American soldiers have landed in France, with hardly a loss worth speaking about? They tried Chlorin gas in a desperate attempt on the Canadians, putting several thousands of them out of the fighting, but as a whole it had no effect upon the war.

Suppose we send ten thousand bombing aeroplanes over Germany. They alone will not win the war. Ten thousand or fifty thousand tanks alone will not win the war. A thousand land battleships or a thousand other fearful land cruisers alone will not win the war. Raining death and destruction upon the civilian population as a rule has only one result: It strives the people to greater deeds, to greater sacrifices, to greater hate, to greater determination to win the war. France, England and Italy are shining examples of this.

No, any one invention is not likely to win the war. Some day, perhaps, some one will invent an atomic ray, which is capable of pulverizing whole regiments at a stroke. Nothing of this sort is impossible. But it is not very probable. Rather it is the wholehearted devotion of the non-combattants to a great and just cause that will win the war. The nation that can throw into the scales the greatest amount of war implements, the heaviest weight of metal, the greatest amount of fighters, coupled with a prodigious use of ALL of the best war inventions will win in the end—PROVIDING THAT EVERY MAN AND WOMAN BEHIND THE LINES CONSTANTLY THINKS AND DREAMS OF WAR AND VICTORY AND IS PREPARED TO PUT EVERY LAST OUNCE OF STRENGTH AS WELL AS ALL WORLDLY BELONGINGS INTO THE RIGH-TEOUS CAUSE WITHOUT STINT OR RESTRAINT.

THE GREATEST WAR INVENTION IS THE FIERY UNDYING WILL TO WIN.

H. Gernsback.
The only way you can become an expert is by doing the very work under competent instructors, which you will be called upon to do later on. In other words, learn by doing. That is the method of the New York Electrical School.

Five minutes of actual practice properly directed is worth more to a man than years and years of book study. Indeed, Actual Practice is the only training of value, and graduates of New York Electrical School have proved themselves to be the only men that are fully qualified to satisfy EVERY demand of the Electrical Profession.

At this "Learn by Doing" School a man acquires the art of Electrical Drafting; the best business method and experience in Electrical Contracting, together with the skill to install, operate and maintain all systems for producing, transmitting and using electricity. A school for Old and Young. Individual instruction.

No previous knowledge of electricity, mechanics or mathematics is necessary to take this electrical course. You can begin the course now and by steady application prepare yourself in a short time. You will be taught by practical electrical experts with actual apparatus, under actual conditions. 5,000 of our students are today successful electricians. Come in and read their enthusiastic letters. Let us explain this course to you in person. If you can't call, send now for 64-page book—it's FREE to you.

SCHOOL OPEN ALL SUMMER.

A Gigantic Exposition and Amusement Park in the Making

The New York International Exposition Which Is to Mark the 300th Anniversary of the Settlement of The Bronx

By GEORGE HOLMES

OURS is indeed an age of wondrous achievement. Altho we are in the midst of the world's greatest war, it is not to be said that we are the least bit doubtful or disconcerted with regard to the ultimate finish.

With the gigantic Merchant Marine now in the making it will eclipse all others and our flag will flutter in the breeze of every seaport in the world.

But to obtain all this foreign trade we must needs have some way of inducing the industrial expositions ever seen east of the Mississippi.

It is to be a permanent enterprise on the general style of Shepherd's Bush and Earl's Court in London. It is destined to be a clearing house of industrial ideas, efforts...
It is to be a vast educational institution for the instruction of the people along scientific, hygienic and artistic lines.

And, withal, a huge recreation center and playground where 250,000 persons can be accommodated each day.

The Exposition will be held each year from May 30 to November 1. The ex-

hibits this year will number about 250, representing eight countries and will be housed in twenty-five magnificent buildings. There will also be Government exhibits from five departments and it is planned to add more each succeeding year.

This vast enterprise is backed and under the guidance of some of the most prominent men of the commercial world in the United States. They believe that the attempt for commercial supremacy will naturally center in New York, hence this location for the Exposition.

The plans for the New York International Exposition are the most stupendous yet conceived from beginning to end. Of the twenty-five buildings some will be devoted to the display of scientific, artistic and industrial triumphs of the world, others to entertainments of the better class.

The exhibit buildings will be known as the Palace of American Achievements, Palace of Fine Arts, Palace of Manufactures and Liberal Arts, Palace of Varied Industries, Horticultural and Agricultural Hall, Mechanical Hall and Automobile Salon. In each of these will be displayed exhibits in keeping with the name of the building.

That these displays will be most interesting is evidenced by the fact that already the United States Government has announced its intention of participating with an exhibit by the Bureau of Mines of the Department of the Interior, and by ex-

hibits from the Army and Navy Departments.

There also will be a department devoted to food conservation, dehydration and scientific cookery, which will be under the direction of Mrs. A. Louise Andrea, one of the best known cooking experts of the United States, who conducted a similar department at the San Francisco Exposition of 1915.

The entire Exposition, however, is not of the serious nature to be found in the Exhibit buildings. The management knows that the people must be entertained as well as instructed, and to this end there are being erected a number of entertainment fea-

tures that bid fair to rival anything ever attempted before, even at an Exposition or Amusement Park.

With the opening date but a short distance away the grounds represent a ver-

itable beehive of activity, there being close

on to 500 carpenters, electricians, painters, plasterers, laborers, supervisors and other officials engaged in making New York's new Exposition a real, live-wire affair. The grounds cover a total of 28½ acres fronting on the Bronx River at 177th Street, a tract of land belonging to William Wal-

dorf Astor. To start with the site re-

sembled a large swamp; by gradual cutting and filling some semblance of order was finally secured, but not until many feet of solid rock had been blasted away to make room for the numerous gas, water, sewer and electric pipes and conduits. For the water supply to the various buildings and fire hydrants, over a mile and a half of main pipes have been laid down, not to mention eleven miles of small water pipes that branch out from the main supply pipe somewhat like the branches of a giant tree.

There will also be a very large number of electrical conduits and as our friend, the publicity manager, said with a mournful note—"three hundred thousand dollars have been buried in these grounds where the public will never see them."

Biggest and best of all will be the amuse-

ment features that will be the delight of the kiddies and make the grown-ups feel like little tots again. First will be the greatest inland pool ever made with real salt water from the Atlantic Ocean. It will be three hundred by three hundred and fifty feet and will have a sand beach three hundred feet long by fifty feet wide, wherein one may acquire a beautiful coat

constant motion by special gears and huge electric motors, producing rolling foaming breakers that bid fair to rival any that his majesty, Father Neptune, ever splashed Coney's bathers with. The pool proper will contain something like 2,500,000 gallons of water and gradually slopes down from the level to a four-foot depth, at which point will be placed the "life lines"; beyond this point the drop is fairly rapid until a ten-

foot depth is reached, where there will be the usual dare-devil platforms, chutes and other swimmers' paraphernalia.

Beneath this deep section on the floor of the pool there is set a series of spaces covered by a heavy glass frame, underneath which will be various colored electric light combinations. These lamps are controlled from shore and when lit up at night present a very beautiful spectacle, not to mention the series of flood and searchlights which will play on the scene.

Perhaps the greatest spectacle of all will be the gigantic illuminated waterfall at the deep end of the pool. At this end there will be a very pretty back-ground of moun-

tains, hills, Alpine houses, mountain streams, etc., and over these will trickle the water and spray, while in the center of this imposing array will be the sheer drop, like a plate of glass from the top of the mountain to the water sixty-five feet below of a dazzling waterfall, which, while a wonderful novelty in itself, will also improve the purity of the water in the pool.

Then there will be a very pretty grotto in back of this waterfall, where one may ob-

serve the seething foam below and the great array of lights.

Besides having the waterfall to purify the water, provision is made so that it can be kept going continuously, thereby adding new and clean water all the time and draining away the old water in proportion. Water is pumped about a mile to the grounds from a point where there is an 11-foot tide, this being right near Long Island Sound. The intake pipe is five feet below low tide; by having it so arranged it is possible to avoid sucking in all the drift and foreign matter which accumulates on the surface. In addition to this there are placed over the opening several metal screens of a very fine mesh. Passing thru the pipes the water will be pumped by the aid of large electric pumps into a large reservoir capable of contain-

ing about five hundred thousand gallons of water. This reservoir is "V" shaped and situated at the back of the pool and the waterfall. Here the water is allowed to

settle and then it is again pumped thru six large lime chloride filters and then thru the pipe line to the top of the "falls," where it is sent hurling over the top into the fountain below. All in all the pumping (Continued on page 267)
Electric Whirling Disk to Start and Stop Aeroplanes

OW that we have instituted a daily aerial mail service between New York and Washington and also between New York and Philadelphia as well as Boston, the matter of making sure that the mail-planes start off on their journey on time is a critical problem. Moreover, the Post Office authorities at New York have bethought themselves that it is really going around the bush to send a flying ground, located fifteen miles from the Post Office in the center of the city. It has been picked up by machines starting to Washington or Boston. He further stated that representatives from several aeroplane concerns had measured the roof of the New York Post Office and reported that in their estimation it was entirely feasible and practicable for the mail-planes to start and alight on the roof thereof. They proposed to build an aeroplane accelerating and decelerating machine for starting and stopping the aeroplanes in such a space, at a cost of something like $50,000. The proposed scheme is illustrated here.

Recently been suggested in the daily press by various writers that some scheme should be available whereby the mail-planes can fly directly over the city and alight on the Post Office building itself, and in this way save several hours daily in delivering the aerial post, as well as gaining a considerable amount of time in starting on their journey.

It was stated by Superintendent of Mails, E. M. Norris, in regard to these suggestions, that it was entirely feasible for aeroplane mail to be dropped on the roof of the New York Post Office, and provided the high buildings of the metropolis would permit the aeroplanes to fly sufficiently low, that the mail could be easily dropped, as suggested, on the roof of the Post Office under most conditions, but that it could not with, and as can be seen, it possesses many novel points. It resembles in general a carousel or merry-go-round, but which the aeroplanes are supposed to be spun around in starting until their propellers have attained sufficient speed and then be suddenly released, when they will be thrown off the disk tangentially by centrifugal force by means of a quick-acting release clutch or better still, by the utilization of powerful electro-magnets arranged around the electric motor-driven disk as proposed by Mr. H. Gernsback in the June issue of the Electrical Experimenter.

This remarkable apparatus is also supposed to prove efficacious in decelerating or gradually stopping aeroplanes as they alight from the air.

In this case there are two schemes which might be employed; the first working on the principle that the rotating disk be driven in an opposite direction to that of the aeroplane, which will in this case tend to quickly decelerate and come to a stop. The second arrangement would be to use large electro-magnets as shown herewith, and in this case the revolving disk could be driven in the same direction as that followed by the alighting 'plane, and by applying the current to the magnets gradually, and thus increasing their strength, the speed of the alighting 'plane and its attached iron arma-
Electric Sirens Warn Paris of Air Raids

AMERICANS are not just yet accustomed to aerial raid warnings, but those who live in cities near the Atlantic Coast are shortly to be initiated in all the arts and graces of "crawling into a rat hole," when the 凡orders it here. The French do not use stoves the way we do; they are accustomed to the chilling air which often blows over this part of Europe and it greatly amuses a Frenchman to see a Yankee shivering like a leaf, and calling loudly for "heat."

The chimney is a long beloved mark of distinction and artistic display on Parisian houses and some are quite large affairs. At last the war has found a practical use for them, for the chimneys, projecting up above the roofs as they do, provide the necessary elevations on which to mount the siren alarm equipment. The acoustic sound waves set up in the air by the siren must have a clear way thru the air in all directions to carry any appreciable distance; they must not be impeded by any obstruction or else they will be greatly weakened, or even dissipated in a very short distance.

These powerful sirens are practically all electrically operated and controlled and involve many unique features. Some of them operate on a blast of compressed air, which is caused to blow a large whistle or vibratory diaphragm whenever a magnetically controlled valve is opened. Others are designed upon the principle of the true siren as found in the physics laboratory, and based upon the fact that if we rapidly rotate a perforated disc in front of a stream of air, such as from a nozzle, then a shrill, whistling sound will be produced and the higher the speed of the disc the higher the pitch of the sound. The blast of air to be thus chomped up by a perforated disc or drum need not be supplied from a source of compressed air but may be that due to the high velocity of a revolving perforated drum, as is the case with the siren illustrated in Figs. 1 and 4. In this design of sound producer there are two similar drums or rings, each perforated with an equal number of perforal openings as shown. The outer drum is stationary, while the inner drum is rapidly revolved by an electric or other motor. The inner revolving drum is designed to give a fan effect and sucks in the air, in this way creating a strong air blast thru the openings in the two drums as they are rapidly opened and closed. The faster the drum rotates, the higher the pitch of the note produced. Some of the larger sirens require a motor of several horse-power, the revolving siren blade measuring 10 to 15 feet in diameter.

The powerful Blériot (French) electric siren of the vertical motor-operated type illustrated at Fig. 3, is interesting. Here

Fig. 1. This Gigantic Electric Siren, Installed on the Tower of Notre Dame, is but One of the Twenty-six Fixt "Aerial Alarm" Sirens Installed All Over Paris to Warn the People.

Fig. 4. First Electric Siren Installed in New York City in the Theater District for Warning Against Aerial Attacks. Many of These Will Be Used Throughout the City.
the base 1 contains the electric motor which drives a vertical spindle or shaft, to which are attached the necessary fan and siren elements within the casings 5 and 6. The air is drawn in thru opening 10. The siren sound waves emerge from openings 6, at the top. An electric "commande" or controller is fitted at the top of this siren, in the cap 7. To this magnetic controller there is connected a circuit linked up with a source of power and a Morse key 9. It is thus possible to actually telegraph with this siren, its shrill-piercing note having been heard at a distance of 2,500 meters or about 1 1/2 miles when the actuating motor and siren drums revolved at 5,000 revolutions per minute.

The internal arrangement of this electric telegraph siren is very ingenious. To shut off the sound rapidly, as in telegraphing, the inventor provides a third or intermediate perforated drum having openings equal in number and size to the usual fast and revolving members. This intermediate drum can be moved back and forth around its axis by means of the electro-magnetic controller 7, so as to more or less line up its openings with those in the fast and rotary drums; the nearer the openings in the three drums align, the greater the volume of sound liberated from the apparatus. The driving motor 1 revolves at constant speed. Where the signals are to be broken up at relatively long periods, say every five minutes, then it is only necessary to utilize a plain type of motor-driven siren, when by opening and closing the motor switch the desired intermittent signals will be given.

Figs. 4 and 5 show an American type of duplex siren, driven by a two-horse electric motor. At one of the southern flying fields in Texas, there is in use a powerful electric siren that gives out the "fog" and other warnings to aviators, which can be heard five miles away.

ACCOUNTING FOR THOSE 100,000 READERS

By Thomas Reed

I t was a big surprise, eh, Bugs, to learn that our Magazine had grown to 100,000 circulation? What do you think of our Little Maggie hot-footing it down the road in a cloud of dust, in the wake of the Saturday Evening Post? I'll say that's going some.

We've got to account for it in some way, same as any other weird phenomenon—make up our minds what it was punched Maggie's accelerator so. And my guess is that it's our Editor's propensity for "starting something."

I'll bet that fellow starts things in his sleep. He isn't satisfied with digging up for us the newest apparatus and processes, and research and theories, but he must have our laboratory-pictures, and "dope" how to make things with nothing to make 'em of, and burned-out lamp competitions—all sort of stimuliants to keep us awake and thinking. If one of his suggestions seems to go dead, no matter, he leaves it and starts something else.

But do they ever go dead? I don't believe so. Now and then one of 'em may appear to bury itself in the soil of Bugdom, like the "dud" shells they talk about, and be lost; but somewhere or other I'll warrant there's an obscure but diligent Bug sitting on the lost idea, prying away at its nose-cap with a screw-driver, bent on making something out of it, and in a fair way to succeed if he lasts long enough.

Different minds are open to different ideas, you see. For instance, mine was never exposed to this utilization of burned-out lamps. I might as well be a wooden man, for all the chance I stand in the contest.

I rack my weary brain, and nothing comes out but an opaque Pool idea, that stands in the door and blocks the passage for anything sensible. What do you suppose it is?—a nest-egg! It's dead wrong—don't let me, I realize it. A china nest-egg's demoralizing enough, but at least it's full of air, and that's the best it's possible to put something inside her product. But an actual vacuum—no; if she ever got wise that people paid money for that sort of contents—good night!

But, because I'm floored is no sign that some other Bug won't come across with a wonderful use for defunct Mardas—something that will lift the mortgage from the home, maybe, or provide Big Sister with a bea. Give him time.

Meanwhile, let's give due credit to our hard-working Ed. Give it to him now, while it's worth something—not wait till he's so obvious that the Sunday supplements are writing him up. If you wait till then before you say "Him? Oh, yes, I usher know him," you're liable to get back a sarcastic "Yes, you did! You knew all the celebrities, didn't you, from Steve Brodie to the Ahkond of Swat!" Wouldn't that be tough, when you really did know him after all?

I'll say right now that I'm looking for some Bug to develop an idea from "E. E." into one of the big inventions of the world. It might surprise the Ed., tho it wouldn't me, if some day one of those conscientious insects should stroll into 353 Fulton Street with a bag full of bills, and remark, "Doc, the wife says your paper was what started my invention, and here's a million dollars she held out of the last pay-envelope for you, with our compliments!" Success to "E. E." and the next 100,000 soon!

*Thanks, awkward, Tom! I compromise with the "insect" on 50% i.e., $490,000, (the $10,000 deduction represents a cash discount of 2%.) If he or it shows up at once! And if the "insect" insists that I take the other 50%—well, I'll not be harsh. I'll get out a fine supplement for the next issue, presenting each reader with a $5.00 W. S. S! For you see, it's the readers who by their support make possible the "E. E."—Tom.*

"GARABED" A FAILURE, SAY GOVERNMENT EXPERTS.

"Garabed," which was to revolutionize the world by the production of an unlimited free energy, is a failure. This was the report of the board of five scientists appointed by congressional resolution, made public by the Interior department July 1.

The report says the principles of the invention of Garabed T. K. Giragosian are unsound.
How Three New York Subways Meet and Pass One Another

Those of us who do not use the great subway systems of the larger cities such as New York are often prone to forget entirely some of the really wonderful engineering work carried out in the bowels of Mother Earth. The subway construction engineers of New York City, and including Brooklyn in this consideration, have solved in recent years some of the most difficult subway construction problems imaginable. This is so for a number of reasons, among which are the present subway plans of this first city of America, calling for a great number of intersections and cross-overs on the different lines, many of which take place under ground. Moreover, some of these underground tubes must be built under existing subways, without in any way interfering with the normal daily traffic. New York City has one of the most extensive subway systems in the world, comprising as it does more than two hundred miles of underground railway. Some of these subway routes which honeycomb the soil of the great metropolis have necessitated the boring of tubes under the East river, at enormous cost, and under difficulties which would seem to require almost superhuman endeavor.

The present illustration shows in a vivid manner one of the greatest subway engineering feats ever performed. Three great arteries of underground traffic now meet at the corner of Broadway and 42nd Street, better known as “Times Square,” and it is at this point, extending over an area from 42nd Street to 46th Street along 7th Avenue and also Broadway, that the new Brooklyn Rapid Transit subway has been constructed, so as to run under the present subway, which proceeds along 42nd Street, and all this work was done without interfering with normal traffic. The entire re-arrangement of the “Times Square” subway station and the interconnecting passageways joining the new B. R. T. subway (running along Broadway) with the old subway, which is to be operated simply as a “shuttle” between “Times Square” and the bird’s-eye view clearly indicates, it proceeds to dip under the old subway line at 42nd Street, but has no track connection with any other subway. The new B. R. T. Broadway line then extends northward to the south end of Central Park, or 59th Street, and from this point it runs directly east across the East River to Long Island City.

The new 7th Avenue subway on Manhattan Island will extend from the Battery uptown on 7th Avenue and will branch into the existing subway system just above 42nd Street and Broadway as the illustration delineates. Express service will be maintained on this route thru the new station at New York City Has Undoubtedly Solved Some of the Most Complex Subway Problems In the World. Here's a Typical Case---At the Corner of 42nd Street and Broadway Three Subways, All Heavy Arteries of Traffic, Meet and Pass on Their Way. The Old Subway Transports its Passengers by “Shuttle” Train from “Grand Central” to “Times Square”. Here They Can Descend to the New B. R. T. Subway, Which Dives Under the Present Interboro Tracks as Shown, or They Can Take a “Seventh Avenue” Express Uptown or Downtown. Counting the Trolley Service, Three Track Levels Are in Use at This Veritable “Hub” of New York’s Traffic.
Searchlights—The Night Eyes of the Army

By FRANK C. PERKINS

The accompanying photograph shows a recent design of American portable auto searchlights as demonstrated at the Marine Barracks, League Island Navy Yard, Philadelphia, Pa. It was also tested out before the Engineering Department at the Washington Barracks, and the Maryland State Militia made very interesting experiments with it in their maneuvers. It is stated that after the first test was made at League Island, a very thorough report was made by the officer in charge, which showed that on a dark night with sleet falling, each lamp gave good illumination at distances up to 1,500 yards. The military officials have taken a particular interest in this auto searchlight because of the conditions in the European war and during the operations of the American Marine Corps at Vera Cruz and Culebra showed the need and the varied uses for such an equipment.

It is pointed out that the features to be incorporated in any portable light must include reliability, ruggedness, ease of carriage and construction of such nature that all of the set may be quickly assembled and placed in operation. This particular auto searchlight in the equipment is mounted on a special body on an autocar chassis. The body is designed so as to furnish protection for the power plant, and to support the four reels of flexible cable, and the spring mounted tracks on which the two searchlight hand trucks rest. These springs are quite essential in eliminating road shocks from the delicate mechanism of the lamps.

It is of interest to note that the power plant consists of a gasoline motor with 4½" x 4½" cylinders, coupled direct to a 7-kilowatt direct-current generator. This generator is designed to run at 1200 revolutions per minute, at which speed it gives 125 volts and delivers 56 amperes. The motor is equipped with a fly-wheel governor, regulating the speed within narrow limits. The motor driving this generator is supplied with its own gasoline tank, and also an independent radiator kept cool by a high-speed fan.

It may be stated that the two hand trucks which carry the searchlights and reels of flexible wire are constructed entirely of steel and aluminum, and have each two wire wheels equipped with 28" x 3" pneumatic tires. These trucks are light in weight and rigid in construction, and so designed that they have large road clearance beneath the light to enable them to be operated in very rough country.

For supplying the necessary current each light carries 1350 feet of cable, divided into two lengths of 675 feet each, so that each lamp can be operated independently of the other at a distance of one-quarter mile from the generating plant. By means of specially designed attachment plugs and reel arrangement, the light can be operated at any distance within the limits of the cable from the power plant without unreeling all of the wire to get to the inner end. The inner ends are arranged to pass through the heads of the drums, so that the attachment may be readily made. Each searchlight measures 14 inches in diameter and has an arc of five thousand candle-power, and is effective up to a mile on a good clear night.

It is declared that in order to get the maximum value of the lamp, the observer of the U. S. Army electric searchlight, fitted with a collapsible steel mast of considerable height. These searchlights are intended for special work and can be removed from the truck when desired. They are fitted with reels of flexible cables as will be seen, these reels maintaining continuous contact with the feed wires from the dynamo at all times, by means of a brush and ring arrangement.

Electric searchlights are invaluable as a protection against enemy air raids upon towns or cities. Since many coast cities are now in darkness at this time, these pictures are of added interest.

One of the photos shows a climbing mast fully elevated. This elevating attachment is used in case the lights are hidden behind trees, walls or bushes for the purpose of concealing them from the enemy observers.

This photo was made at the Mobile Anti-Aircraft Section of the Engineering Corps, Washington Barracks, Washington, D. C.

The third photo illustrates a battery of searchlights in operation at night locating aeroplanes that are sent up for the purpose of detecting enemy aircraft.
Aerial Mono-Flyer of the Future

By H. WINFIELD SECOR

ELECTRICAL EXPERIMENTER
August, 1918

THE high-speed electric train of the future will undoubtedly be radically different in design from the railroad cars of the present day. For many locations, especially in mountainous regions, a electrically operated mono-rail car, illustrated on our front cover as well as on this page, will prove of particular value. Begin with this aerial mono-flyer is enabled to run along at speeds of 200 miles per hour or faster on a single rail or cable, thanks to the wonderful stabilizing effect, which is of a size and is being easily capable of maintaining a 100-foot car in an upright position on a mono-rail or cable. Among other interesting technical features of this thoroughly practical passenger carrier are the airplane propeller drive, unique method of supplying electric current to the car motors, safety attachments to prevent the car from deranging should the gyroscope fail, and a number of other interesting details, based on sound engineering principles which our technical experts are quite familiar with, but which have not as yet found practical application.

The mono-rail flyer is not as impractical as would at first appear for such a single-rail car carrying passengers had been operated by Brennan, the English engineer, many years ago. His car, fitted with a small stabilizing gyroscope, travelled along upright on a single rail very successfully. If you wish to demonstrate this remarkable power of the gyroscope go to the nearest toy-shop and purchase a 25 cent gyro. You will find that if you stretch a piece of string horizontally or at an angle that the upright gyro, spinning at high speed, of course, will travel along the string upright.

Another important fact is that as the gyro's speed decreases it counters gradually more and more, which action you can readily demonstrate yourself; moreover, this shows that if the mono-flyer's gyroscopic should fail at any time then the car would cant over easily, not rapidly, owing to the great momentum which the gyro wheel. Thus it is the decentering gyro and car slowly reach a neutral or hanging position, which it will safely assume when provided with guard rails such as those on a typical electric car illustration.

An ingenious arrangement of the inner passenger compartment of the monoflyer has been given. In emergency conditions, and this involves the free suspension of this compartment on roller bearings as indicated in the end-wise sectional view of the car. The inner cab is not free to rotate on its axis normally, but as soon as the gage in front of the motorman here shown, or over regular mono-rail land systems, is by high-speed air propellers. This idea may not seem feasible at first but the practicability of the scheme is attested by the gigantic Caproni triplanes, as well as the English monoplane planes, some of which have as many as four propellers and a carrying capacity of fifteen to twenty passengers. The mono-flyer propellers are driven by electric motors controlled by the motorman at the front of the car.

The next proposition is how to supply the car with current. There are three methods by which the car can be electrically operated. The first is to employ a gasoline-electric power plant; in this unit a petrol motor drives a dynamo and the current delivered by it is supplied to the propeller and gyroscopes motors thru regulating rheostats in the usual manner. The second scheme is the one illustrated herewith in which the positive and negative currents are carried by two special duplex cables, so wound as to eliminate static electric charges continuously along its surface. A specially contrived plus and minus contact trolley wheel rolls on this double polarity cable, thereby permitting positive and negative electric currents respectively. Owing to the peculiar construction of this contact wheel, with its spiral shoes and the spiral arrangement of the opposite conductors in the cable, the circuit is completed effectively. Either direct or alternating current can be utilized.

A third way of supplying electric current to the mono-flyer is by the one-wire, high tension, high frequency system of Tesla. In his works on high frequency currents Dr. Tesla shows and describes a high frequency system which he built and demonstrated successfully. This method of distributing electric energy is ideally applicable to our present railway. The steel cable upon which the car travels could be charged by a high frequency, unidirectional current and the motors operated on the Tesla one-wire method. Also, to intensify the corona transmission light feeder cable could be run along just above the car, the two cables being oppositely charged with a high tension, high frequency current. The corona leakage between such highly charged conductors is enormous, and not easily appreciated by anyone who has never seen such a discharge. This corona is but a silent effluence and will fill the air space between two opposite charged conductors separated 6 to 8 feet apart, when charged at 150,000 volts. A number of the long distance transmission lines of today utilize voltages of this order, and the reader may gasp when he thinks of what might happen if our mono-flyer was rolling along peacefully between two cables charged at 200,000 volts and a short-circuit should occur. Well he might hold his breath if the current were of 60 cycles frequency, for then there would be some fireworks. Sixty cycle current kills. But this same 200,000 volt alternating current if oscillating at half-a-million cycles per second would be harmless. Besides, the passengers in the steel car would not be shocked by any shock as the currents, in the event of a short-circuit, would pass thru the steel frame.

Two views of a Sperry ship-stabilizing gyroscope of the electric motor-driven type are illustrated herewith as of interest to readers of this article. The sectional view shows the motor mechanism inside the casing of the 24-inch diameter rotor. The motor is an A. C. squirrel cage induction motor. The gyro is fitted with a motor-operated vacuum pump which keeps the gyro chamber exhausted of air, in this way eliminating considerable losses due to the windage of the massive high.
speed wheel. The precession of such gyroscopes is taken care of automatically by a special motor gear as shown in the sectional view. Here A is the heavy steel rotor wheel, revolving on a vertical shaft B, by means of the squirrel cage induction motor C. A heavy roller bearing D carries the thrust load while the radial bearings E transmit the gyroscopic loads thru the case F to the gudgeon G, secured to the ship's or car's structure. Great gyros of this type and measuring 20 to 25 feet have been successfully installed on large battle-ships to prevent their rolling in a heavy sea, and thus provide a steady platform from which the big guns could be accurately fired. The wonderful stabilizing power posset by even the smallest gyroscopic can be gleaned from the fact that in computing the size of gyro for stabilizing a certain ship, the engineers figure on the complete gyro equipment to weigh about one per cent of the ship's total displacement. Thus for a 500-ton craft the gyro equipment would weigh but 5 tons while for a 10,000-ton battle-ship it would be only 80 tons or eight-tenths of one per cent.

The idea as here exprest is susceptible of many improvements to be sure. For one thing it is not conceivable that we have found the most efficient form of a propulsion mechanism at all. Possibly the air propelled craft of the future will have propellers shaped like huge augers and worm their way thru the air—who knows?

WILLIAM J. HAMMER NOW A MAJOR IN U. S. NATIONAL ARMY.

It is with extreme pleasure that we can announce that Mr. William J. Hammer, Consulting Electrical Engineer of New York City, and who has contributed numerous interesting electrical articles to the Electrical Experimenter in the past several years, has been appointed a major in the U. S. National Army, and is at present located at Washington, D. C. The U. S. Government is to be congratulated upon obtaining the services of so distinguished and accomplished a scholar as a co-worker to aid in solving the many diversified problems now besetting it. Mr. Hammer, who was for a number of years an early associate of Thomas A. Edison in the development and application of the electric light, has traveled extensively in Europe, and is therefore thoroly conversant with electrical inventions and developments both in Great Britain and on the Continent. Major Hammer may be addressed in care of the Inventions Section, War Plans Division, General Staff, War College, Washington, D. C. He received his appointment on June 4th, 1918.

THE VALUE OF A KILOWATT AND HOW TO SAVE IT.

By John J. Dempsey

Vice-President Brooklyn Rapid Transit Lines.

WHAT is a kilowatt?

In terms of economy—of power saving—which is in a double sense a burning issue to every industry and the nation at large today, a kilowatt represents the consumption of three pounds of coal.

In the much-discuss matter of heat, for instance: The operation of trains without heat requires four kilowatts per car mile. With three points of heat on, it requires between live and one-half and six kilowatts per car mile. Thus the heating of a car requires 30 per cent of the power required to operate it.

Obviously, then, it is the duty of every conductor to keep in mind the amount of energy wasted in the opening and closing of doors. With due care in this regard alone, a proper temperature could be maintained in the cars on from one-third to one-half less power.

During the cold weather conductors on surface cars should keep the rear doors closed as much as possible and, during non-rush hours, ask passengers to use the rear entrance entirely, thus keeping the front doors closed and contributing to the comfort of passengers. When conductors find it necessary to confer with motormen they should be careful not to stand with head and shoulders thrust out thru the open front door, but should rather step onto the front platform and close the door behind them.

Motormen, for their part, should remember that every time a brake is applied a certain amount of energy is taken out of the train, and that to restore it a further consumption of power is necessary. When a motorman, running thru a congested district, or where cars are blocked, keeps "nosing up" by throwing his power on and off to the jerky accompaniment of the brake, he might as well be shovelling coal out of the Company's bins, or money out of the Company's pockets into a ditch. The Company could really better afford to pay such a man to stay at home and not work at all.

Proper and economical operation requires a motorman to use his brake as seldom as possible consistently with safety and to coast as long and as frequently as possible consistently with his schedule.

So far as the public is concerned, it is perhaps not unnatural for persons who have no sense of the amount of coal necessary to operate a system like the Brooklyn Rapid Transit to think, because we have what seems a great quantity of coal in our bins that is sufficient to operate almost indefinitely and furnish ample heat as well. But that is only because they view the situation from the standpoint of their own coal consumption. If they stopped to think that it takes one and a half tons of coal to run one five-car train from Union Square to Coney Island and back and that two such round trips consume more coal than the average family uses in a year, they would, if fair-minded, be disposed to withhold judgment.
Reclaiming the U-Boats' Toll: A Novel Novel Salvage Operations

The toll of sunken ships occasioned by the advent of unrestricted U-boat warfare promises to be a large one by the end of the war, in spite of all of the anti-submarine devices and protective measures which have been promulgated and put into active practice. As we approach the close of four years of the World War we may well admit that the problem of reconstructing which will come to our hands in the great aftermath of the World War that we shall be confronted with is evidently formidable and an undoubted need of a greatly increased tonnage of ships to carry much needed supplies to the various countries now being devastated. Therefore, as we cannot build ships sufficient fast to catch up with the gigantic shipping requirements which are sure to face us the day after tomorrow, yet we shall need but one other ultimatum—that is, to devise some means of accurately locating and raising the hundreds of ships, both large and small, which have been sunk by the enemy submarines.

There has been a veritable flood of patents issued in the past few years on many ingenious and impractical schemes for raising sunken ships. In the present instance we shall examine the claims of three recent patentees who aim to provide apparatus for locating and raising the victims of the greatest submarine warfare ever conceived.

The first patent concerns a powerful telescopic electric searchlight for locating and insubmersible submarines. The device, in its simplest form, consists of a powerful motor or engine to generate electricity from water or other sources, a large storage battery to power the motor, and a series of electrical cables or wires to conduct the power to the searchlight itself. The searchlight is mounted on a tripod or similar support, and is directed towards the location of the sunken ship. The operator of the searchlight, sitting in a cab or similar enclosure, operates the machinery and controls the searchlight. The light from the searchlight is directed downwards, illuminating the bottom of the water, and allowing the operator to locate the ship and determine its position.

Another object of the invention is to provide a telescope of the character illustrated and having an improved form of the objective fitted with a ring of power, increasing the power of the light and making it more efficient. The telescope may be mounted in any convenient manner and may be used in conjunction with the searchlight.

The second patent is for a searching and locating machine for sunken vessels. The device consists of a powerful electric motor, a series of cables or wires, and a searchlight. The searchlight is mounted on a tripod or similar support, and is directed towards the location of the sunken ship. The operator of the searchlight, sitting in a cab or similar enclosure, operates the machinery and controls the searchlight. The light from the searchlight is directed downwards, illuminating the bottom of the water, and allowing the operator to locate the ship and determine its position.

The third patent is for a method of locating sunken ships. The device consists of a powerful magnetic coil, a series of cables or wires, and a searchlight. The searchlight is mounted on a tripod or similar support, and is directed towards the location of the sunken ship. The operator of the searchlight, sitting in a cab or similar enclosure, operates the machinery and controls the searchlight. The light from the searchlight is directed downwards, illuminating the bottom of the water, and allowing the operator to locate the ship and determine its position.

In order to operate this large exploring searchlight, the operator is equipped with a loud-speaking telephone running to the engineer's post on the large carrying the operator, which he can use to turn or move his position while inspecting a wreck, or when issuing orders to the engineer for raising or diverting the telegraph cables or wires. For the electric lamps is derived from a small dynamo driven by the steam engine of the vessel, or it can be supplied by storage batteries.

The telescopic searchlight just described is for the purpose of inspecting salvaging operations, or for locating sunken ships, etc., while the illustrations at Figs. 'B' and 'C' show two novel schemes devised for the actual work of salvaging a submerged wreck.

The salvaging apparatus illustrated in Fig. 'B' was invented by Mr. John D. Hilliard, of Glens Falls, New York. This idea involves one of the most ingenious applications of electro-magnetism that we have encountered for some time. We referred to this invention in a recent issue of the ELECTRICAL EXPERIMENTER as the "wireless pug" and the "sound-controlled electro-magnetic mechanism" devised by Mr. Hilliard can only be known by one name—"sand-hog," for sand-hog it certainly is. The series of operations to be carried out in Mr. Hilliard's ship salvage scheme is somewhat as follows:

1. First, provides an electro-magnetic, self-propelled double-ended pilot, called a "sand-hog," as we may call it. The detailed view of this most ingenious mechanism is shown at the right of Fig. "B." In brief, this almost human electro-magnetic pilot comprises a small double-ended truck or carriage attached to one end of a powerful electro-magnetic field which is self-propelled by electro-magnetic control wires, etc., may be carried. It is also possible to project a compert air or high pressure water blast thru this flexi-ble casting, which is fixed on the bottom of the wreck in front of the sand-hog. The wheels of this curious looking self-propelled pilot are somewhat like the revolving rings of a hydro- static (water pressure) or electric motor controlled from above. Powerful electro-magnetic coils encircle the steel axled wheels, magnetizing them powerfully. Thus, we see that a very curious and novel condition is provided, viz.,—that as the electric coils revolve around the motor, either backward or forward as may be desired, these same steel wheels are strongly magnetized owing to the effect of the magnetic field. When the sand-hog will therefore, if lowered into the water near the side of a submerged iron hull, tend to crawl along the surface of the water without slipping.

Armed with this semi-intelligent mechanism, the salvage engineers proceed to lower the magnetic pilot, and its attached cable from the working barge in such a direction that the sand-hog will take hold of the steel side of the ship and start working it in the direction of its own motion. The illustration at Fig. "B" clearly indicate, the sand-hog manages to cling to the steel surf-ace of the ship in any of the combinations of circumstances. It can compress air or water jet blast, a path is cleared for it continuously thru the mud or sand in which the hull may lie. It is evident that as the magnetic pilot progresses it will blow a channel or trench for itself clear around and under the bottom of the hull, until it is once more in a vertical position on the opposite side of the hull.

When the sand-hog has reached the position described, it can be moved back to the side of the barge at the time, and in this way the bottom of the hull can be blown in a narrow channel, which may then be widened by divers and the water pumped out. The salvaged ship can then be towed to the nearest harbor where the work can be completed.

The scheme for raising sunken vessels illustrated at Fig. "C" is due to Mr. Charles B. Dawson, of Seattle, Washington. Mr. Dawson's ideas are in some ways quite elaborate, but he has them well worked out, and while in some cases it may be rather (Continued on page 280)
VARIOUS SCHEMES FOR RAISING SUNKEN SHIPS

(For full description see opposite page)
WHY Sparks had stopt reading the New York Evening World: He contemplated his old meerschaum pipe meditatively while with his long and lankey index finger, stained by many acids, he carefully rubbed a long, thin and quivering nose. This was always a sign of deep, concentrated thought of the nose's owner. It also, as a rule, induced the birth of a great idea. Again, and very slowly he re-read the article, which millions that same day had read.

disturbances affected all telegraph and telephone lines extending between Chicago and the eastern cities. On telegraph wires of the Postal Telegraph Co. without regular battery being applied at terminal offices, grounded lines showed a potential of 425 volts positive, varying to 225 volts negative; the disturbance continuing between 12:15 A. M. and 9:15 A. M.

At Newark, N. J., in the Broad Street office a Western Union opera-

for you had uttered five words. His clear blue eyes, lying deep in their sockets, sparkled with life and intelligence and what Sparks did not know about electricity was mighty little indeed. I believe there is no electrical book in existence that Sparks had not devoured ravenously in his spare hours, while having lunch or else while in bed, in the small hours of the morning. His thirst for electrical knowledge was unbounded, and he soaked up every bit of information like a sponge. Yes, and he re-

... The President of the Glorious French Republic Shouts Dramatically: "Messieurs... le jour de Gloire est Arrivé... VIVE-LA-FRANCE!!"—and Throws in the Huge Switch With its Long Ebonite Handle. ...

casually, without a quiver, let alone, a nose quiver. The newspaper item was simple enough:

NEW YORK, Aug. 10, 1917—An electromagnetic storm of great violence swept over the eastern section of the United States last night. Due to a brilliant Aurora Borealis—the Northern Lights,—telegraph and long distance telephone, as well as cable communications were interrupted for hours. No telegraphic traffic was possible between New York and points West. It was impossible to work any of the transatlantic cables between 12:15 A. M. and 9:15 A. M., every one of them having "gone dead." The Aurora Borealis

tor was severely shocked, trying to operate the key, while long sparks played about his instruments.

Sparks rose excitedly and began pacing the cement floor of the vast Tesla laboratory, totally oblivious to the fact that he was sucking a cold pipe. The more he paced about, the more excited he became. Finally he flung himself into a chair and began feverishly to make sketches on big white sheets of drawing paper.

"Why" Sparks had been just an ordinary "Bug," an experimenter, when he entered Tesla's great research laboratory at the beginning of the great war in 1914. Tesla liked the keen, red-haired tousled boy, who always seemed to divine your thoughts be-
tained it, too. In short, the young prodigy was a living electrical cyclopedia and highly valued by his associates. No wonder Tesla in three short years had made him superintendent of the laboratory.

Of course, Sparks' first name was not really "Why." But someone had dubbed him with this sobriquet because of his eternal "But why is this,""Why, why should we not do it this way"—"Why do you try to do that?" In short his first word always seemed to be "Why"—it had to be, in his unending quest for knowledge. And his "Why" was always very emphatic, explosive-like, imperitive, from which there was no escape.

Ah, yes, his first name. To tell the honest
truth I don’t know it. Last year in the spring when I went up to the laboratory, I thought I would find out. So when I finally located the young wonder, behind a bus he was standing, fixing it, blue sparks by means of a screwdriver, I told him that I intended to write something about him and his wonderful electrical knowledge. Was I glad enough to give me his real first name?

He was watching a big fuse critically, and mundane-minded manner exploded: "Why?" That was his question. So for all I know his real name is "Why" Sparks.

We left Sparks with his drawings, in the laboratory. That was on a certain evening last fall. To be exact it was about 10 o’clock. At 10:05 Tesla accompanied by two Army officials strolled out of the laboratory where Sparks was still feverishly engaged with sketches lying all about him. Tesla who was working out a certain apparatus for the Government had dropped in late to show Major General McQuire the result of six weeks’ labors. The apparatus had just been completed that day and the General, a military electrical expert, had come over specially from Washington to see the "his work." But before Tesla had a chance to throw in the switch of the large rotary converter, Sparks had leaped up, and was waving excitedly, large sparks flying in Tesla’s face. He gushed forth a torrent of questioning and for fully five minutes Tesla and the two Army officials were listening spell-bound to the young inventor driven to a frenzy; two of the three men were speechless, looking awestruck at Sparks, who having delivered himself of his latest outburst, now became normally cool as a cucumber.

It was Tesla who first found his voice. "Wonderful, wonderful. Absolutely wonderful. Sparks, my boy, you will be the most talked of man on this planet. And his idea is sound." This to the General. "Absolutely without a flaw. And so simple. Why, oh why? did I not think of it before? Come, let me shake the hand of America’s youngest and greatest genius!"

Which he did.

There then followed an excited thirty-minute conversation with the two army men and an endless long distance talk with the War Department at Washington. Then there was a rush trip to Washington by Tesla and Sparks, conferences at the War Department, and finally a few days later Sparks was summoned to Washington. When he was presented to the President, who was highly enthusiastic about the model which Sparks and Tesla had contrived to the head of the Nation. Still later there were certain rush orders from the War Department to the General Electric and Westinghouse Companies for big, queer machines, and these same machines were shortly manufactured.

But here the Censor bids us an emphatic "Halt. One may not even now divulge certain military information. You appreciate that."

* * *

Baron von Unterrichter’s flying “Circus” was getting ready to bomb a certain American city that day. The American city of late had shot down entirely too many of the Baron’s flyers. Only yesterday von der Gacken, an American ace himself—and one of von Unterrichter’s old friends had been downed, and killed right inside of the German lines. So the Baron was very bloody this sunny morning. As he put it:

"Verdamnte Yankee Schweinehunde,* we will show them who is master of the air hereafter! Toting off his hat to the American lines beyond.

*Sie, Müller,” this to an orderly.

"Zu Befehl, Herr Lentzmann,” replied the young orderly as he came on the run, clicking his heels together, hand at his cap.

"Vorwärts, Port!” barked the chief, as he hastened Müller off to summon post haste every man of the aerial squadron for the usual conference before the attack.

In less than two minutes all the flyers were standing drawn up at military attention before their chief, forming a half circle about him. Von Unterrichter’s instructions were clear and definite. This was a re- ral raid; von der Halberstadt’s death must be avenged, fearfully avenged. No quarter was to be given.

IN THE SEPTEMBER “E.E.”
YOU WILL FIND:

"New Aerial Lasso to Destroy Enemy Aeroplanes," by H. Gernbach.

"Telephoning Directly To From Moving Trains," by S. Stoddard, an expert on Wave Meters.

"Artificial Diamonds and Rubies—How They Are Made in the Electric Furnace." by Dr. J. A. Glass.

"The Phenomena of Electrical Conduction in Gases V—Weighing on Ton," by Rogers D. Rusk, M. A.

"How to Build a Switch-board—How to Build a Real One," by Harlan Danner.

"Operating Modern Current Circuits—A Clear Exposition of All the Usual Problems," by Arno A. Krage, Instructor in Radio, University of St. Louis.

"Direct Reading Radio Chart Which Solves All Calculations in Wave-length, Inductance and Capacity," prepared by a Marconi Radio Engineer.

* * *

"Dieses Amerikanische Gesindel!"—here his voice rose to a screechous tenor that caused me to respect us, as never before. The orders are to bomb every American base hospital within the sector.

All this several of the men recited involuntarily, which did not escape the keen eye of von Unterrichter, who now incensed to blind fury, by this show of "mercilessness," as he put it, exhorited his men in his harriest possible terms. "And as for their flyers, you must not give quarter. They will be fitted with all or some of the machines. Kill them! Schietss die Lumpen zusammen! Pump nickel into them, if you see that they may land unhurt. In this, I am the director of all flying etiquette—a thing abhorred by any decent flyer as a rule. It is bad enough to have your machine shot down, but "sitting on a disabled enemy’s tail," pouring machine gun fire into a helpless man, strug-
Electricity and the Range-Finder in War

As many people are aware, the matter of determining accurately the range between a certain gun or battery of guns and the enemy target, is a very important factor in all military operations and naval maneuvers. Not so many years ago when the range of artillery was quite insignificant compared to that of today, the matter of range-finding as it is known, was an unknown study. All that the officer in charge of a gun battery had to do in those days was to check up the first few shots fired and by watching the effect and the point hit by the projectile thru his telescope, or in many cases simply with the naked eye, the particular gun firing the shots could be readily elevated or lowered so as to change the trajectory of the projectile. But in the past twenty-five years the hit and miss principle of range-finding has been done away with, and a number of more or less accurate range-finding instruments developed, some of which are very ingenious indeed, and extremely accurate for comparatively long ranges.

The photograph herewith shows one of Uncle Sam's latest types of accurate range-finding instruments installed on board a modern dreadnought. The Jackies are shown in the act of determining the range of an object which has been selected as a target for the ship's giant guns, several of which can be seen in the background protruding from their turrets. The operator peering so intently into the eye-piece of the range-finder, and who is wearing a pair of sensitive telephone receivers as well as a transmitter strap to his person, is one of the most important men in the crew of any fighting ship whether large or small, for if he makes an error in reading the dials of the range-finder, then the enemy may escape being hit. As becomes evident, time is the essence of every naval engagement, for in a few minutes time the enemy if not disabled by your own guns will in all probability plant the major part of a broadside attack on your superstructure and gun deck, possibly disabling your own battery.

Thus we see that the man at the range-finder has a very important mission to fulfill, when he straps the head "phones" and

left prism telescopes can be trained on the distant object, and the refracted rays from the prisms are put thru a pair of objective lenses in the manner illustrated. These right and left rays pass along thru the center of the black-slipper tube and meet in the center where there is positioned two central reflectors. At this juncture it is well to note the two views shown in the circles at the bottom of Fig. A. These two views show the image of a distant target (a church) as it appears in the eye-piece of the range-finder, before the right and left prisms are adjusted to "coincidence" and "after coincidence," the latter or right hand view being the one observed by the range-finding officer at the point where the instrument indicates on a specially calibrated dial the correct range in yards. As will be noted from Fig. A, the upper semi-circular image is the one reflected by the left hand prism. A dividing line separates the two images, and in the present case the instrument is adjusted until the tower of the church slides along toward the left until it is exactly in line with the remaining portion of the tower appearing in the lower image.

So much for the physical action of the "one-man" range-finder. But this does not tell us yet just how the range is determined, excepting that we have learned that when the images coincide, that the instrument indicates the range in yards on a calibrated dial. Probably we will do best to go back a few years to the time of the Boer War in South Africa. At that time the English Army had considerable range-finding to do among the Kaffirs of "Coxe Paul's" country. Briefly explained, the "two-man" range-finder then used works after the fashion illustrated in Fig. B. It must be considered before going further, that every

(Continued on page 278)
WOMEN TO LEARN X-RAY WORK.

It seems that with the war's progress, and its constant inroads upon our male population, it behooves itself upon the women-folk who are left at home to in some way fill these vacancies, so that the speed of war preparations may be kept up to the highest standard.

Also it is to be noted that a steady drain is being made from the ranks of technically trained men which of necessity cripples to quite a large extent the wheels of industry. Women have been excluded from the regular service of both the Army and Navy with a few exceptions, such as Yeoman, etc.

MOBILE X-RAY NOW USED AT FRONT-LINE TRENCHES.

The Committee on Public Information, Division on Woman's War Work, issues the following:

The X-ray is now carried to the front-line trench for the benefit of wounded soldiers, so that no time may be lost in ascertaining the condition of wounds. The Army Medical Department has developed a mobile X-ray outfit, carried on a standard Army ambulance slightly modified.

This outfit includes an X-ray table, a dark room, and a complete set of apparatus for the localization of foreign bodies. Fully as expert work can be done with this mobile outfit as in any base hospital X-ray department. Its use in this field makes it possible for the surgeon at the front to send a complete report of a soldier's condition when a man is transferred to a hospital back of the lines.

ELECTRIC MACHINE MAKES FIFTY YARDS OF BANDAGES A MINUTE.

The machine being operated by this nurse is expected to revolutionize the making of gauge bandages. It is the invention of J. A. Butler, of Boston, and has been installed in the New England Surgical Dressings Committee workroom.

According to reports the machine is working very satisfactorily. It produces two sizes of folded bandages, one four inches and the other three inches wide. They are folded four or eight times as desired. The machine is capable of turning out 50 yards of bandages in a minute depending on the skill of the operator, which is a great deal faster than the usual method of hand manufacture.

but it is undoubtedly a fact that their services would be much in demand in civilian walks of life were they properly trained to fill the constantly growing vacancies.

Foremost in the ranks of institutions who have started in the work of training women for war work may be mentioned the Hunter College of New York City. We have published from time to time the activities of the women folk in the radio service, including the training of drafted men. Now a new branch of scientific study is about to be placed at their service and one that will yield a substantial remuneration for the time and expense of the course, while at the same time aiding the country in its fight for Democracy.

The course is a special term from June 3rd to August 10th in X-ray work. So far there have been several hundred requests for admission to the course but the school will only be able to handle a limited number of classes. There will be ten students to a class and in making up these classes preference will be shown to those who have been nurses or are acquainted with medical practise. This was only decided upon after due consideration, and it was shown that those already having some training would be all the quicker able to fill the many vacancies at present.

The installation of the apparatus will be taken care of by a large New York X-ray apparatus concern and the cost will be near the three thousand mark. It will be of the best and capable of a very wide range of work.

The course itself will be under the supervision of Dr. Raymond Bartlett Earle. Dr. Elise Fox, Roentgenologist in charge, City Hospital, will be the X-ray instructor, and an advisory board of prominent doctors and surgeons will complete the list. There will be an afternoon course and open to one in the evening consisting of the following subjects: X-ray, including the action, care and operation of the machine, anatomy, French conversation and physics lectures, after which will come the hospital observation in which the students will act as assistants in the taking of actual X-ray photos.

The course will be very thorough, making it necessary for one undertaking it to apply oneself conscientiously to the serious work in hand and none but those attaining a mark of eighty per cent or more will receive a certificate. It is not to be doubted that all taking it up will have the ambition to make good in order that the government may call upon them when necessary.
How Birds Take Their Own Pictures Electrically

By Dr. E. Bade

It is difficult to take good animal pictures in the open for the simple reason that the camera sees differently than the human eye. The various colors of nature do not sensitize the film in proportion to their light values, and since the film is color blind, it interprets little more than light and dark.

The difficulties of approaching the animal one desires to photograph can be surmounted with the following electrical device. This contrivance consists of three dry cells, an electric bell, a small electromagnet, and a contact or switch box. The contact box consists of a strong wooden base upon which is screwed a support for a movable scale-like contrivance. A strong wire rod, or a long nail, is used for a pivot. One arm of the scale extends about four inches. At the extremity of this arm a light twig is fastened. Just behind the pivot the other arms slope gently downward and ends in a box-like receptacle into which stones, pieces of iron, or lead are placed, so that this end little more than counterbalances the other arm. The first arm, to which the twig was fastened, also carries the contacts which only closes the circuit when a bird is sitting on the branch. As can be seen from the accompanying drawing, the wires carrying the current are here interrupted and flattened. One end of the wire is rounded into a shallow groove, while the other is flat. Just above the two flattened wires is a "V" shaped piece of copper, supported by a piece of wood which in turn is fastened to the movable scale-like arm. The "V" shaped piece of metal fits loosely between the wooden support and slides with its heavier end in the groove. When the twig is pushed downward the lighter end of the metal touches the flattened wire. This closes the circuit.

The camera is placed upon a small table or an especially contrived tripod upon which the electro-magnets are fastened. The camera used in this case was a Graflex, having a push button which releases the shutter. A large angle iron was taken, a knob placed at one end, and a weight at the other. The knob was adjusted so as to come into contact with the push button, while the weight at the other end of the iron was increased until a slight pressure released the shutter. The magnets were then placed upon a projecting support so that they came within an eighth of an inch of the angle iron.

The camera is now focust upon a twig or any other suitable object fastened to the arm. The instant a bird hops upon the twig the circuit is closed and the magnet is energized, instantly drawing the angle iron downward. This releases the shutter and the photo of the bird is secured.

It will be found advantageous to introduce an electric bell into the circuit as it instantly rings when a picture has been taken, thus enabling the operator to reload the camera at once.

It will be found that certain birds frequent certain places more than others. Now, in order to secure a variety of birds, an electric push button is also introduced into the circuit. This button is placed at a little distance from the camera but still within sight of it. When the operator sees a bird advancing towards the contact box, he presses the button and the picture of the animal will be taken, provided that the birds jumps upon the twig. When he sees that other birds are in the vicinity which he does not desire to photograph, the push button is released. Should the bird hop on the twig, the circuit will not be closed, and no picture will be taken, since the circuit at the push button remains open. But press the button and the picture of the bird is instantly taken.

Of course, this device must be placed where from previous observation birds have been frequently seen. These places are usually found near or at bird-houses or bird-baths. The birds can also be attracted to certain places by food. This is placed out a few days before the camera is used so that the birds will become accustomed to this contrivance.

Big Turbine for New York.

The United Electric Light and Power Company of New York City has recently placed an order with a large Pittsburgh electric manufacturing company for a 22,000 kilowatt turbo-generator set. The gigantic generator will be rated at 25,900 kva, at 85 per cent power factor, 8,000 volts, 3-phase, 62% cycles. It will be direct-connected to a steam turbine. The order includes a 40,000 sq. ft. surface condenser and the usual auxiliaries.
The Electrical Women of England

By ALBERT H. BRIDGE

(Electrical Correspondent, The Electrical Experimenter.)

QUITE early in the war it became obvious to the British Ministry of Munitions that if fighting men were to be released from industry without reducing the output of war requirements, women must take their places. Those of us who have been more or less closely and sympathetically observing the course of events have all along known something of the difficulties that have lifted their ugly forms and spread themselves across the path of progress; we also know with what tact, adaptability and determination each new critical situation has had to be negotiated. Prejudices from employers and prejudices from workmen, had to be broken down at a bit at a time, and all the while headway had to be made with the suitable training of educated and other women. Only the most imperative demand of absolute necessity made the change possible so that it may be said that under the influences of compulsion we have been able to secure practical experience of inestimable engineering value which we might not have had in decades of normal operations.

Gradually our women were brought under training for special operations, and work to which women had never previously put their hand was soon proved to be well within the compass of their strength and their adaptability. In practise such results have been obtained as should demolish absolutely all prejudices so far as individual or ultimate efficiency is concerned. Just now, when still more men of military age are leaving the bench for the camp and the trench, experience and necessity are working hand in hand.

It was, of course, no new thing for women and girls to be engaged upon many small electrical manufacturing operations. Years before the war the writer had witnessed their efficient employment in electric wire and cable factories, in armature winding work, electric motor manufacturing,knowing, in conduit and switch work, and in the making of numerous small accessories. In one case in London a factory was run for a time in which crippled girls, exclusively, were engaged in the manufacture of electric lamps in which substitutes for platinum formed a special feature. But where in the old days ten women were engaged in electrical manufacturing activity, there are now thousands of them and the number of operations, or classes of service rendered by them, have increased correspondingly.

By courtesy of the Ministry of Munitions the writer is able to illustrate some typical examples of what English women are doing in electrical works. Before the war we regarded with distinct amusement a novel experiment in which we read in the electrical press that at some small out of the way station in the States a woman part-proprietor ran the plant. We even looked upon it as a freak—perhaps you Americans did so too—but such is not the case today. We now have women working in some of the largest power stations in the United Kingdom. Experience with them on the whole is not unsatisfactory, yet I believe I should feel pretty safe if I had to predict what would happen in this particular connection after the war.

One of the accompanying photographs shows a woman engaged in electricity works service—in charge of a switchboard for 500 kilowatts. I recently inspected the most complete and educative official collection of specimens of electrical work the product of women skill and labor—and I saw photographs of women engaged in charge of a 1,000 horsepower steam engine, another attending a 300 kilowatt direct coupled engine set, others building small commutators, operating presses for armature winding, erecting switchboards, driving 40 ton cranes, driving electric trucks, conducting electric welding operations, making electric con¬necting masts, making parts for internal combustion engines, sparking plug parts, magneto!s, lampholders, lighting switchboards for marine machinery, etc.—indeed a mere catalog of the different occupations in which they are engaged, tho it would prove their multidudinous and multifarious nature, would be monotomous. Yet what is happening in the electrical world is but an illustration of the dexterity, skill, ability and willingness that women are demonstrating every day in a host of other departments of industry directly or indirectly connected with munitions production.

The position up to date is: there are 950,000 women engaged in munitions produc¬tion! Mr. Ben H. Morgan, who was for two years Dilution officer under the British Ministry of Munitions gives us to understand that they are turning out nearly one-third of the total output!

NAVAL AVIATION WIDE OPEN FOR YOUR TRADE.

"Here's a chance to enroll in the United States Naval Reserve Force and work at your own trade. The naval aviation section needs a great number of men immediately. Good ratings and good pay are possible for qualified men. Here is the list of ratings and the necessary trades.

Machinist's Mates—General machinists, automobile mechanics and assemblers, toolmakers, diesmakers and similar mechanical trades.

Quartermasters—Cutters and cloth fitters, upholsterers, canvas workers, painters, tent riggers.

Carpenter's Mates—Woodworkers of all kinds.

Blacksmiths—Toolsmiths, forge men, furnace men, etc.
There exists in the heavens, at a conservative estimate, from half a million to a million nebulae that are visible in the greatest telescopes. A very few of these, notably the Great Nebula in Orion, the Great Spiral Nebula in Andromeda and a particularly bright nebula in the Southern Hemisphere can be faintly distinguished without telescopic aid. So extremely faint are the great majority, however, that it requires all the light-gathering power of the most powerful telescopes, aided by photographic exposures of several hours' duration, to bring out the details of their varied and intricate structure.

Altho the nebulae are most diversified in their general appearance, they may all be classified into three groups: the vast irregular nebulae, the comparatively rare planetary nebulae, and the mysterious spiral nebulae. Members of the first two groups are strictly gaseous in their nature, but the last group, which includes by far the greater number of all the nebulae, has characteristics that seem to point to an entirely different origin.

In fact, it may turn out that the spiral nebulae are not nebulae at all. This most puzzling group which has been the subject of an unusual amount of investigation and discussion in the past few years will be treated of separately in another article. We will consider here only the true gaseous nebulae—the planetary and irregular nebulae.

Gaseous nebulae can be distinguished by the nature of their light which gives, when examined with the spectroscope, what is known as a bright-line spectrum. According to the first law of spectrum analysis such a spectrum is characteristic of incandescent gases shining only by their own light under low pressure. What these gases are can be determined from the positions of the lines in the spectrum, since to each chemical element belongs always the same line or set of lines in the spectrum. It has been found that all gaseous nebulae are composed of hydrogen and helium gas and an unknown gas found only in gaseous nebulae and named for that reason neblium. This peculiar gas is characterized by a bright line in the green part of the spectrum that gives a greenish tinge to the gaseous nebulae. They are for this reason sometimes referred to as the green nebulae to distinguish them from the white or spiral nebulae. It is believed that the presence of neblium may be due to some form of electrical excitations existing in extremely rare gases.

The irregular nebulae are, there is every reason to believe, the primordial stuff from which the stars are made. They fill a tremendous volume of space but possess very low density and small total mass. This is evident from the fact that they are certainly as distant as the stars, with which they are frequently associated and yet they cover an apparent space in the heavens that would be filled normally by hundreds, or in some cases thousands of stars. When we consider that the average diameter of a star is about a million miles and that within a sphere whose radius is, according to Newcomb, 412,500 times the radius of the earth's orbit (the radius of the earth's orbit being 93,000,000 miles) there exists but one visible star, on the average, we begin to realize how enormous must be the volume of space filled by the vast irregular nebulae. Were they not of small mass and low density, their gravitational force would be so great that they would draw to them all the neighboring stars.

Estimates of the densities of the gaseous nebulae are usually placed between one...
hundred thousandth and one millionth of the density of the earth's atmosphere. It has been found very difficult to explain how the luminosity of the gaseous nebulae is maintained under the conditions of extremely low temperature and pressure that must prevail everywhere, except in the more central portions of the nebulae. It is believed that the light of the gaseous nebulae must be due partly to some form of electrical excitation. It is not understood, moreover, how the nebulae can show the complex structure that characterizes them under the force of gravitation alone. Some other forces such as electrical repulsion or radiation or light pressure must be at work as well.

Irregular and planetary nebulae bear a strong resemblance to each other in some respects, yet they are different in others. Both types show a marked preference for the plane of the Milky Way, the fundamental plane of the sidereal universe. They are found most frequently where the star clouds are densest, and they are as often as not associated with stars that are classified as young stars. They are never connected with stars of advanced type. The stars enmeshed in the gaseous nebulae are the helium stars, or as they are frequently called the Orion stars, because they occur in such great numbers in the Great Orion Nebula and its extensions. They are characterized by their extremely low density and intense blue light. Great star groups such as the Pleiades and the chief stars of the constellation Orion are sometimes enwrapped in one vast irregular nebula which often condenses locally around conspicuous stars of the group. At the very center of the Great Orion Nebula is a multiple star of six components that is beyond a doubt physically connected with the Great Nebula. All the conspicuous stars of the Pleiades are surrounded by a faint nebulous haze, which stars to show brightly by reflected light from these stars and partly by its own luminosity. Portions of these great irregular nebulae are non-luminous; dark streaks and lanes are frequently observed in the bright gaseous nebulae, particularly devoid of stars as if dark absorbing matter shut off the light from stars lying beyond. Observations of the Great Orion Nebula have shown a whirling motion of its parts, the as a whole this vast nebula is almost stationary in space. This brings us to the most marked point of difference between the irregular and the planetary nebulae, that of their motion thru space. The irregular nebulae are the most slowly moving of all celestial objects, being practically at rest or simply drifting thru space, while the planetary nebulae are to be classified among the most rapidly moving objects in the heavens, their speed averaging much higher than that of the stars. The planets are also extremely small as compared to the irregular nebulae, receiving their name from their resemblance to faint planetary disks. They are usually associated with a single star or show a star-like condensation at the center. There are, moreover, comparatively few of these objects, not more than one hundred and fifty being catalogued up to the present time. The latest observations seem to indicate that these small nebulae have arisen as a result of some celestial collision or cataclysmous haze bearing a strong resemblance in composition and general appearance to the planetary nebulae.

The spectrum of the planets is, on the other hand, very similar to a certain rare class of stars known as Wolf-Rayet stars. These stars, the Novae and the planetary nebulae are all closely confined to the plane of the Milky Way and some relationships between the three classes of objects may be traced as a result of further observations.

We may now briefly summarize the

The Phenomena of Electrical Conduction in Gases

Part IV—Why Ions Disappear

By ROGERS D. RUSK, M. A.

The behavior of the electrically charged particles of a gas is at times almost magical in nature. Unseen forces may suddenly produce them and other unseen forces may as suddenly make them disappear. The scientist who wishes to know whether or not a gas will conduct electricity must first know whether there are any ions present in the gas. If he wants to know just how much electricity will flow through the gas, he must also know how many ions have been produced and how many have disappeared. It is a well-known fact that if an ionized gas is allowed to stand for some time it will in some way lose its ions and its power to conduct electricity. This seemingly mysterious phenomena, however, can be very easily explained by two words—diffusion and recombination.

Diffusion is the scattering of ions and then migration of a cloud of ionized gas through field lines of force, lose their charge and recombination is the reuniting of the ions of a molecule again. The numerical figures which represent the rates at which these processes continue are called respectively the coefficient of diffusion and the coefficient of recombination.

In order to obtain these coefficients or rates of disappearance of the ions it is necessary in some way or other to count the ions or determine their relative numbers at different times. An ion, however, is far too small to be visible even in the highest powered microscope. Moreover it is too small to ever be visible to the human eye. That may seem like a rash statement in this day and age of scientific miracles, and yet it must be remembered that the human eye is only sensitive to certain wave lengths of light. Now the ion would either reflect only a single pulse of light which would give it neither size nor shape, or it would reflect waves of light many, many times too short to affect the human eye. As long then as the human eye retains its present limitations, the ion will remain invisible. Notwithstanding the fact that we cannot see these particles we can prove their presence by means of the electroscope or electrometer, and we can obtain a measure of the total number present by measuring the total effect on the instrument. Much work of this kind, including the determination of the above two coefficients, has been done quite recently by the world’s leading physicists, including J. S. Townsend and J. J. Thomson of England.

Recombination is a very natural consequence of ionization and as its name implies, means the recombination of positive and negative ions just after they have been formed. For instance when a neutral molecule experiences the force of some ionizing agency it is torn asunder and forms two equal and oppositely charged ions; now these oppositely charged particles attract each other according to the laws of electric attraction, and if they are not suddenly driven far apart by some force, this attraction will cause them to reunite and thus form neutrally charged molecules again. This can be shown diagrammatically as in Fig. 1, where each stage of the action is shown. In any ionized gas then, where there are equal numbers of positives and negatives, recombination will finally remove the conductivity of the gas. If there are unequal numbers of positives and negatives, the rate of recombination will depend upon the relative numbers of each. If the ions are removed from the field as fast as they are formed, that is by a saturation current, recombination will not take place. If, however, there is no electric field acting to remove the ions, the number will increase until they are so close together that they recombine as fast as they are formed or, in other words, the rates of recombination and ionization are equal; then the gas will have reached a steady state and the number of ions will be a maximum.

Scientists define the rate of recombination as doing this mathematically as and put it equal to where is called the coefficient of recombination and is the number of ions of either sign present. It can be seen that is merely a constant which expresses the relation between the rate of recombination and the number of ions present. As the amount of current which will pass thru a gas depends upon the number of ions present in the gas and the number of ions depends upon the rate of recombination, then the current depends on the rate of recombination.

One of the earliest determinations of the coefficient of recombination was made by E. Rutherford in 1897, by the use of a metal tube similar to the one shown in Fig. 2, by blowing a current of ionized air thru it and measuring the conductivity at different distances along the source. For instance if the current from electrode C to E, is one-half what it is from A to E, then half of the ions have disappeared and the time taken for them to disappear was the time for the gas to travel from A to C down the tube. The only measurement it is necessary to take are the currents thru the gas at A and C, and the rate of flow of the gas from A to C. The rate of recombination has been found to vary with the different methods of producing ions, showing that the kinds of ions that are produced, vary with the nature of the gas, and with the temperature and pressure.

Under certain conditions the disappearance of ions by diffusion is even greater than by recombination, hence it must be taken into very careful consideration. Diffusion is the thinning out or migration of ions which may be due to the following causes: If there is a greater density of ions in one part of a certain volume of gas than in another part, the ions will spread out toward the less dense part. If ions of one sign only have been generated in a gas, any adjacent particles being of similar charge will repel each other and all of the ions will tend to spread as far away from each other as possible. This is true of like ions when both positives and negatives are present. Then when ions by any means approach the wall of the containing vessel or any

(Continued on page 279)
FARMERS LEARN ELECTRICITY.
The University of California is teaching farmers to use electricity. In the near future the indications are that the efficiency of electricity on the farm will be generally recognized and adopted.

PHOTOGRAPHING AUTO PARTS WITH MERCURY VAPOR LAMPS.
A complete and accurate catalog of parts is one of the necessities for every automobile manufacturer. Every detail must be illustrated, either separately or assembled with others into one of the parts of the car. A unique method of taking the photographs necessary for these catalogs has been worked out by a prominent automobile manufacturer.
The use is made of an elevated platform under which can be placed a large flat wooden table. On this are arranged various items, each with its appropriate title and number, printed on a card, laid beside or below it. The boundary of the photograph is marked by black wooden strips. Thru a hole in the platform the photographer focuses his camera upon the display below. Light is furnished by four mercury-vapor tubes, hung underneath and near the edges of the platform. Due to the highly actinic quality of the mercury-vapor light, the exposure is much shorter than with other illuminants having the same apparent brilliancy.

This arrangement possesses numerous advantages, among which are that it enables the various parts to be associated with descriptive text, or explanations of the workings of complex apparatus. Much greater speed can be made in getting out instructions, since only one photograph need be taken of the entire group. Photographing from above is also very much quicker than from in front, because the parts can be much more easily arranged on the horizontal platforms and removed or rearranged for the next picture, than where it is necessary to tack up the parts on a vertical background.—Courtesy Willys-Overland Co.

ELECTRICAL EXPERIMENTER

HUNS HAVE DEVICE TO HELP U-BOAT CREWS TO SURFACE AFTER WRECK.
Dutch newspapers describe a new method by which crews of U-boats escape from their boats to the surface after they have been destroyed or wrecked. Statistics prepared by the German Admiralty show that, despite popular belief, a submarine runs less danger in its operations than does the cruiser or other ship of war, and that despite the terrific strain, there has been a very small loss of life among the crews.

When the U-boat is wrecked or disabled and lies on the bottom of the sea a little compartment on top is opened and a buoy which has been filled with air is released and at once rises to the top, carrying attached to it a steel cable. Equipped with "swimming vests," also inflated with air, the men climb to the surface by means of the cable. During this climb to the surface each man wears over his mouth and nose a small apparatus containing pure air, so that he is enabled to breathe oxygen. This apparatus at the same time purifies the carbonic acid, and keeps the air pure for several hours. The buoy on the surface also is equipped with an electrical apparatus so that electric waves can be sent thru the water calling for assistance. The buoys are large enough to accommodate nearly all the men of the crew.

When danger threatens the alarm is at once sounded and this new life-saving apparatus is at once prepared for use, so that the men can leave a U-boat within a few minutes. It is said that this apparatus will make the operation of the U-boats as safe as can be desired for their crews. Thus it seems the Germans do find time to invent safety devices.

ELECTRIC CHICK PICKER.
A machine invented by O. G. Rieske, of Buffalo, picks an ordinary fowl naked in less than five minutes. Moreover, no feathers are scattered. A small electric motor turns a suction fan, and also a roller contained within the instrument itself, the power being transmitted by means of flexible cable. The roller is hollow and its outer surface is pierced by a number of slits which permit the incoming blast produced by the fan to pass freely thru it. The top of the instrument is hooded and attached to this hood in a little rubber roller which rests firmly against the surface of the large drum-like wheel. The feathers of the fowl, sucked up against the two rollers, are plucked by having to squeeze between the rollers, after which they are blown to a tank. A thumb contact permits the hood to be moved around on its axis, and thus the relative positions of the two rollers are adjusted according to the needs of each case. The smallest wild fowl or the biggest turkey may be plucked with equal ease. A fowl can readily be picked in the dry state, but ordinarily it is scalded.

EMISSIVE PROPERTIES OF TUNGSTEN.
The emissive properties of tungsten have been investigated by two methods. One investigation consisted in the determination of the selective reflection of plane, highly polished mirrors of tungsten in the visible and in the infra-red spectrum. A depression was found at 0.8 in the reflectivity curve, which is the cause of a marked selective emission band found in incandescent tungsten.

The second investigation was on the selective emission of straight and helical filaments of tungsten, in which it was shown that the increased brightness within the helix is due almost entirely to multiple reflection. The most important deduction is that the radiation from within the helix is not sufficiently close to that of a uniformly heated inclosure to be used in the calibration of pyrometers.

Photographing Automobile Parts With Mercury Vapor Lamp and Camera Set Vertically Above the Objects, Thus Saving Much Time in Arranging the Display.
A NEW TELEGRAPHIC SIGNAL LAMP FOR MOTOR-BOATS.

In the accompanying illustration a telegraphic signal lamp is shown which is now being offered by a Boston concern. This lamp as illustrated consists of a 7-inch by 10-inch brass anchor light with "Fresnal" lens. For use with it in signaling, a specially constructed Morse key is provided with heavy platinum points, the base of which encloses a condenser connected across points of the key to prevent arcing and to shorten the lag between make and break. An attachment plug and cord is provided so that the signal can be connected to any voltage electric circuit. It is very substantial and will stand any weather.

A PORTABLE ELECTRIC AIR COMPRESSOR.

Here is a novel and efficient electric air compressor that is really portable. It is built as a compact unit, with electric motor, high pressure compressor and transmission all enclosed in one frame. All one has to do is plug in the nearest lamp socket, either direct or alternating current, connect the hose to your tire and turn on the switch. The particular features in the construction of this portable compressor are that it is built as an integral unit, self-contained in a metal housing; its efficiency is increased by means of forced air draft ventilation, operated automatically, keeping the motor and cylinders cool at all times. There is no water to freeze or to evaporate.

The motor is of the compensated series, interpolated type, which will operate on either direct or alternating current, so that a different machine is not required every time you move.

The wick feed system of lubrication is used.

NEW SELF-CONTAINED MICROPHONE BUTTON.

If standard transmitters cost only a trifle, and were not much bigger than a thimble, every repair man could carry a few in his pocket. Then when a subscriber's instrument failed to work for reasons unknown to the subscriber, and the repair man's ten mile trip disclosed a faulty transmitter, he could take a new one out of his pocket, screw it into place, and be on his way.

A Chicago inventor, J. Skinderviken, has so nearly approximated this desirable condition that he is desiring in the way of transmitter repairs. He has been allowed a patent on a self-contained transmitter button which meets practically all the conditions of our first problem. Externally the button is merely a cone-shaped bit of brass with a threaded stem, a nut and a lock-nut to fit the hole in the standard transmitter diaphragm.

It has at least one paramount advantage over the regular transmitter. It takes equally well in all positions—vertical, horizontal, inverted, or at any angle. The method of repair used with this unique microphone button is to remove with a small screw-driver the metal bridge common to all standard transmitters. This bridge the repair man puts in his pocket, to be referred later to the scrap heap. The button then is screwed directly to the transmitter diaphragm, without any support but its own screw stem. The whole affair can be executed in little more than a minute.

This universal position feature makes the Skinderviken button very useful also in repairing hand-microphones, which are commonly subjected to the most severe distortions of position. The same is true to a lesser extent of the desk stand.

NEW BATTERY SWITCH FITTED WITH SPRING BINDING POSTS.

A one point and two point wooden battery switch which is equipped with the spring binding posts are now on the market. The handle of this switch is made in one piece and all the metal parts of it, including the binding posts, are fastened to the wooden handle by means of eyelets. This, it is pointed out by the maker, eliminates all screws and does away with the loosening of any parts. The switch can be quickly wired on account of the convenient construction of the spring clip binding posts which are employed, without the use of any tools.

A NEW MILKING MACHINE.

This new electric milking machine profits by all the mistakes made by others, it is claimed. The new milking machine has no rubber milk tubes. It is suspended under the cow and can't be kicked off; nor can the teat cups drop off and suck up dirt. It can milk a three- or two-tested cow as easily as a four-tested one, and can milk each teat independently. It has an exclusive type—three-sided inflation that positively insures a three-sided collapse from tip of teat to udder. It does not milk four teats at once, but two at a time. Alternately.

The milk from each teat passes thru an unbreakable, transparent, straight celluloid tube that is easily cleaned. You can see the milk flow, and as each quarter is milked you can stop the action on it. These small unbreakable tubes take the place of the long rubber hose, an essential part of most milkers, and insure getting milk always as clean and pure as it is in the cow's udder. It also has a float valve that absolutely prevents the milk being drawn back to the vacuum tank if the pipe becomes full.

And it can be operated by an electric motor and in conjunction with any lighting plant.

The teat cups are radically new in design and exert a compound action; first it sucks milk from the teat by vacuum and then shuts it off completely by atmospheric release, exactly duplicating the natural hand method. —Photo courtesy Western Electric Co.
Experimental Physics

By JOHN J. FURIA, A. B., M. A., (Columbia University)

Lesson 14—Current Electricity

A current is the flow of electric charge in motion. In an electric current, the terminals carry an electric current. (This was Oersted’s experiment.)

The Voltaic Cell—It Produces an Electric Current by the Chemical Action of Dilute Sulfuric Acid on Zinc and Copper.

Copper +

Zinc

White sulfuric acid

The terminals carry an electric current. (This was Oersted’s experiment.)

That the terminals of the cell are electrically charged before they are connected, can be shown by use of the electroscope of Lesson 13. On testing for the sign of the charge we find the copper + and the zinc —. See Fig. 73.

Experiment 81—Allow the current from a voltaic cell to pass thru a vertical wire (see Fig. 74), and sift small iron filings around the wire. We find that the magnetic field consists of concentric circles lying in a horizontal plane. On exploring with a small compass we get results as in Fig. 74. On reversing the current the compass reverses. The direction of the magnetic field (the direction in which the N pole of a compass points) is related to the direction of the current by the right hand rule which is stated as follows: "Grasp the wire in which current is flowing by the right hand so that the thumb points in the direction in which the current is flowing; then the magnetic lines encircle the wire in the same direction as do the fingers of the hand." If instead of passing the current thru a single vertical wire we allow it to pass thru a wire with a paper tube around it and iron filings are sifted around it, the filings are deflected vertically.

The Electrometer—An instrument for measuring electric charge. It is called a Faraday Disk. The Faraday Disk is an electroscope with a long stem. When charged, it will deflect through a greater number of degrees with each additional charge. On grounding it, the charges are equalized and it returns to zero. The basis of all instruments used in measuring electric charge is the Faraday Disk. A practical instrument showing how the current in a conductor sets up magnetic whirls is Oersted’s experiment. "Grasp the wire in which current is flowing with the right hand so that the thumb points in the direction in which the current is flowing; then the magnetic lines encircle the wire in the same direction as do the fingers of the hand."

The Electric Lamp—When electricity is allowed to pass thru a wire, light is produced. This is called incandescence. A. V. Seeley has invented an instrument for measuring electric charge. It is called the Faraday Disk. The Faraday Disk is an electroscope with a long stem. When charged, it will deflect through a greater number of degrees with each additional charge. On grounding it, the charges are equalized and it returns to zero. The basis of all instruments used in measuring electric charge is the Faraday Disk. A practical instrument showing how the current in a conductor sets up magnetic whirls is Oersted’s experiment. "Grasp the wire in which current is flowing with the right hand so that the thumb points in the direction in which the current is flowing; then the magnetic lines encircle the wire in the same direction as do the fingers of the hand."

The Compass—An instrument for measuring magnetic fields. It is called a compass. A compass needle placed in the center of a magnetic field will become deflected. This is the basis of all instruments for measuring magnetic fields. A practical instrument showing how the current in a conductor sets up magnetic whirls is Oersted’s experiment. "Grasp the wire in which current is flowing with the right hand so that the thumb points in the direction in which the current is flowing; then the magnetic lines encircle the wire in the same direction as do the fingers of the hand."

The Galvanometer—An instrument for measuring electric current. It is called a galvanometer. When calibrated to give the strength of current directly it is called an ammeter. The ammeter has low resistance so as to oppose the passage of electric current. Therefore, it practically nil obstruction. Because of the practically nil obstruction, all the current passes thru the wire. We get a true measure of it. The ammeter or instrument for measuring electric pressure is called the galvanometer. It is a sensitive instrument for measuring electric pressure. The basis of all instruments for measuring electric pressure is the galvanometer. A practical instrument showing how the current in a conductor sets up magnetic whirls is Oersted’s experiment. "Grasp the wire in which current is flowing with the right hand so that the thumb points in the direction in which the current is flowing; then the magnetic lines encircle the wire in the same direction as do the fingers of the hand."

The Voltmeter—An instrument for measuring electric pressure. It is called a voltmeter. The voltmeter has high resistance so as almost to oppose the passage of electric current. Therefore, there is practically nil obstruction. Because of the practically nil obstruction, all the current passes thru the wire, and we get a true measure of it. The ammeter or instrument for measuring electric pressure is called the voltmeter. It is a sensitive instrument for measuring electric pressure. The basis of all instruments for measuring electric pressure is the voltmeter. A practical instrument showing how the current in a conductor sets up magnetic whirls is Oersted’s experiment. "Grasp the wire in which current is flowing with the right hand so that the thumb points in the direction in which the current is flowing; then the magnetic lines encircle the wire in the same direction as do the fingers of the hand."

October, 1918
COMMERCIAL wireless lost a pioneer from its ranks when John Bottomley, third vice-president, secretary and treasurer of the Marconi Wireless Telegraph Company of America, died in the Post Graduate Hospital, New York, on Sunday, June 10th. Mr. Bottomley was in his seventy-first year.

John Bottomley, Director, Marconi Co., Dies

Twenty years of ceaseless activity in the radio field are credited to the deceased, for it was in 1898 that he first met Marconi and took up the responsible task of introducing wireless telegraphy to the American world of commerce. In 1902, he became the active head of the American Marconi Company. At the time of his death he was vice-president and a director of the associated Marconi Telegraph-Cable Companies, treasurer of the Pan-American Wireless Telegraph and Telephone Company, treasurer and director of The Wireless Press and treasurer of the Marconi Institute. Mr. Bottomley had been president of the New York Electrical Society and was an active member of the Engineers Club, vice-president of the

ELECTRICAL EXPERIMENTER

August, 1918

Notice to All Radio Readers

As most of our radio readers are undoubtedly aware, the U. S. Government has decided that all Amateur Wireless Stations, whether licensed or unlicensed, or equipped for receiving or transmitting, shall be closed.

For the convenience of our readers we are giving this notice on page 244, so that those who are interested in the ELECTRICAL EXPERIMENTER, for the reason that we desire to continue to publish valuable articles on the wireless art from time to time, and which may treat on both transmitting and receiving apparatus. In the first place, there are a great many students among our readers who will demand and expect a continuation of the usual class of Radio subjects, which we have published in the past four years, and secondly, there will be hundreds and even thousands of new radio pupils in the various naval and civilian schools throughout the country who will be benefited by up-to-date wireless articles treating on both the transmitting as well as receiving equipment. Remember that you must not connect up radio apparatus to any form of antenna.—The Editors.
MEMORIZING THE CODE.

I read with interest "A Short-cut to Code Learning," in the January number by Thomas Reed. I will try to describe a method used by the Swiss Boy Scouts that has proved very successful, and, in fact, so successful that it is the only way they know the code.

Each letter of the code is represented by a word that begins with the same letter, so as to simplify recognition. Also each "dot" or "dash" of the code is represented by a syllable (of the word). And, last, every syllable containing the vowel "o" means a dash in the code.

A few examples will make the process clear. Take for instance — B — - - = Bonaparte. Bonaparte contains four syllables, of the first syllable contains the vowel "o" which means that the letter in the code begins with a dash; the other syllables do not contain "o" and therefore are dots.

Thus:

G = Gondole =
A = Arnold =
H = Hilarité =
F = Farandole =
S = Sardine =
M = Moto =
E = Ehrie =

I will not give the equivalents for all the alphabet, as all these words are unfortunately in French and would be of no use, but it would be easy with enough time to make one up in English.

However, I do not think learning the code by these methods are efficient, as they only help the beginners more or less easy to the beginner and later he will have to memorize it, the usual way.

II. STARTING RECEIVING

I think that simplifying receiving would be of some help to the beginners and the method I will now describe is very useful. This method is also used in Switzerland by the Boy Scouts. (I do not know if it is used elsewhere.) And I think not only helping beginners in wireless, but it would be of service for heliographic receivers.

This method requires a chart containing the alphabet and numerals (see illustration). The letters are divided into two groups—those beginning by a "dot" and those beginning by a "dash.

A also a straight line (—) represents a "dash" and a dotted line a "dot" (. . . ). Thus when a letter begins with a "dot" look at group I and if with a dash at group II. This chart explains letter A (—) .

(1) Look at group I. (2) As the next symbol is a "dash" follow the straight line and we come to A.
(3) Take the letter Z (—). (4) Look at group II. (2) Follow the straight line. (3) Follow the dotted line. (4) Follow the dotted line. Thus to find the letter we pass thru T, M, G, and Z.

BOYS' WIRELESS SEIZED: NAVY GETS TWO RECRUITS.

Zas-szxx) (*!-*-?.szszxx- ss-splutter!
"German spies," gasped a neighbor as he heard the hissing noise and watched the sparks flashing from the home of Mrs. Pat-rick O'Shaunessy, at New Canaan, Conn.

Again came the hiss and the spark. The neighbor jumped to the telephone and the next day Federal raiders swooped down on the O'Shaunessy cottage. Mrs. O'Shaun-

nessy sobbed a plea that her only boys, William, twenty, and Thomas Francis, eighteen, be forgiven this time. But the raiders frowned. It was against the law for amateurs to fow with wireless apparatus in war time. "Schucks," laughed Tommie, "we were just studying so we could get in the navy wireless branch."

The Federal officials learned the statement was true, but had to confiscate the machine. They suggested in leaving that the boys could get practical wireless experience without interference by joining the navy. "That's what we will do," agreed the boys. And they did. Mrs. O'Shaunessy pre-

sented herself to Chief Ycwoamn Mrs. George Wheelock at the Naval Recruiting headquarters. She had Tom in tow. She explained she had tried to keep the boy at home, but had to yield.

Tom was found to be 100 per cent physi-

One Uncle Sam needs you!!

NEW "GLASS SLATE" FOR TEACH-

ING HOOK-UPS.

Patents have recently been applied for in various countries on a drawing slate invented by a Canadian Wireless Instructor.

The wireless student who has learned to draw the connections of apparatus arranged always according to a particular plan, in-
vitably encounters trouble when presented with a diagram representing the same pieces of apparatus placed in entirely different positions with respect to each other, and it is only then that he realizes he has wasted considerable time in merely accustomed himself to repeatedly drawing the same connect-
ing lines in the same order, without grasping their meaning.

The present invention, a direct product of necessity, takes the form of a framed sheet of ground glass, beneath which representations of the various parts comprising a wireless or other electrical equipment, printed in heavy black lines upon blocks of

This, I think, is the easiest method to decipher a code and by looking at the dia-
gram it is readily understood. Hoping this will interest some amateurs.

AN IMPROVED CONDENSER SCALE.

The drawing shows a special graduated scale which, when substituted for the condenser scale, will show the exact position of the condenser for each number of taps of the secondary. As you will notice by the drawing, as the turns of the secondary are increased the condenser is brought nearer zero, and in the case of NAA the more taps are taken off the greater the condenser capacity used. This, of course, is naturally necessary, but the idea of the arrangement is to show when, for instance, four taps are used the condenser scale will be at an indicated point. By this method, after noting the scale where different stations come in, it will be an easy matter to tune in these same stations again when desired.

I have been using this method to great advantage, especially when time is the prime factor, that is when one wishes to listen for two or even three stations at once, by merely changing the secondary taps and a lot of unnecessary time formerly lost by moving the condenser to the exact point and having to hunt for each one is saved.

UNIVERSITY OF PITTSBURGH GIVES RADIO ENGINEERING COURSE.

A course in Radio Engineering for technical graduates is being given at the University of Pittsburgh which comprises a term lasting eight weeks. This course will be open only to graduates in electrical or mechanical engineering who are recorded in Class I of the National Army Draft. Men enrolling in it will be placed by the Government in Class V until completion of the course, when they will be inducted into the Signal Corps and sent to an army school for further training. The need for men familiar with the technique of radio-communication is great, and the chances for obtaining a commission ultimately are good. There will be no charge for tuition, but students must provide their own living and travel expenses.

As the number of men is limited, application should be made at once to Prof. H. E. Dyche, Department of Electrical Engineering, University of Pittsburgh, Pittsburgh, Pa.

ELECTRICAL EXPERIMENTER

HOW TO USE SHORT INTERRUPTER RODS.

Procurce a miniature coupling from an Erector building outfit, take an alloy rod that has become too short for ordinary use, put this thru the hole in the cover, take off the tube from the interrupter, and place the coupling in the tube with a piece of straight copper wire A in one end, and alloy rod C in the other. Replace tube and...

VICTROLA NOW TEACHES WIRELESS.

One of the largest talking machine companies has just announced a special course of instruction in wireless telephony by means of disc records and accompanying books of instruction. In announcing the course the company says in part: United States Army and Navy are in need of thousands of skilled wireless operators, and a complete course of study may be carried on by means of these records, and every students is paid a very small fraction of the expense that is ordinarily involved. The course consists of six ten-inch double-faced records with book of instructions.

A SOMewhat DIFFERENT ROTARY SWITCH.

Many amateurs are building receiving sets with a receiving transformer using rotary switches for regulating the number of turns of wire in use. These switch knobs and assemblies are quite expensive when bought, but can be easily and cheaply constructed at home without machine tools of any kind. The material needed will be a piece of one-fourth inch rubber or fiber sheet, a brass backing bolt with the nuts, a binding post as shown in the dotted line in the drawing, and some spring brass for the lever of the switch. Determine the size of bolt you wish, lay out the circumscribed and the proper diameter on the fiber or rubber, and then cut out the disk. A heavy gasket cutter will help do this if the knob is made of fiber. If hard rubber is used, it can be cut out by chipping off pieces with pliers till a rough disk is secured. Then this is filed down till perfect round.

Drill a hole in the center and in this place a long battery binding post, whose flat end has been filed smooth and polished. Fasten it with a nut that has been rounded, to match the round handle. Then cut a piece of spring brass to the desired shape, making it narrow at the outer end. Punch a hole at the wide end and fasten it on the bolt in the knob by means of another nut.

Next drill a hole in the board or panel on which the switch is to be mounted. This hole should be large enough to admit the binding post shown in the sketch, but not so large that it will slip. Attach a collar or wide part slip thru. A binding post of this kind can be found in practically every experimenter's shop. It is threaded at both ends to fit a battery bolt. Push the small end of this binding post into the hole, then from the rear insert a binding post on which a washer and a nut have been placed. Draw up the binding post into the hole by means of the nut at the back. Then screw the knob screw into the hole in the binding post at the front far enough so that it will not have any play and so that the blade makes good electrical contact with the switch points. If a little judgment is used in designing the layout of the switch and contacts, it will work better than many high priced switches, and will be just as serviceable.

Analysis of Irregular Wave Shaped Alternating Curves
Harmonics—Part II
By Prof. F. E. Austin
instructor of electrical engineering, Thayer school of civil engineering, dartmouth College

According to the discovery of Fourier, any periodic or regularly recurring wave of any shape whatever, is in reality the resultant obtained by adding together a number, usually a large number, sometimes an infinite number of sine waves, one of which has the same frequency or same periodic time as the original or resultant curve.

Any alternating current or pressure of any shape whatever, according to Fourier's theory, is made up of the sum of a definite number of simple sine waves of current or pressure, having various amplitudes and different wave lengths or frequencies.

Many surprising results may be obtained by simply arranging sine curves on cross section paper and adding algebraically their heights at various points and drawing a curve through the points so located. This may be illustrated by Fig. 1, in which three sine curves are arranged as indicated, and their amplitudes added together algebraically forming the resultant curve, drawn in heavy lines. It may be noted that if at any chosen position two or more sine curve heights are positive, that is extend above the horizontal datum line, then the sum of the sine curve heights extending downward below the horizontal datum line must be subtracted from the sum of the sine curve heights extending above the datum line. If the sum of the downward or negative heights exceeds the sum of the upward or positive heights, then the point of the resultant curve is located below the datum line. It may happen that the sum of two negative heights may have to be subtracted from a single positive height. Any irregular but periodic curve of current or pressure, meaning one that repeats the same irregular shape during each succeeding interval of time, may be exactly reproduced on paper by the proper selection of sine curves. Fig. 2 shows an alternating curve made up of four simple sine curves. The building up of such irregular periodic resultant curves is called synthesis. Of course, it is not possible to build up curves of any particular shape until it is definitely known exactly how many sine curves are necessary; their frequency, their amplitudes, and their starting points relative to each other. The determination of the number, frequency, amplitudes, and position of the component sine curves making up any resultant curve is called analysis; which is a somewhat complex operation; depending upon certain known mathematical relation and physical laws.

It may be well to consider for a moment why an alternating current or an alternating pressure does not have a perfectly simple pressure wave, which may be obtained from a generator depends at each instant of time upon the speed of the moving inductor line, the strength of the magnetic field thru which the inductor is moving. If for example the motion of the inductor should be perfectly uniform, but the field should be variable, then the induced pressure would vary accordingly; on the other hand should the magnetic field be perfectly uniform, but the motion of the inductor be variable then the resulting induced pressure would be irregular to conform. Again both of the variable conditions might act simultaneously, either in unison to increase the induced pressure or in opposition to reduce it.

There may also be other causes of pressure and current distortion resulting from apparatus connected into the generator circuit; such as condensers, motors, telephones, and coils of all kinds.

As it is often desirable and necessary to obtain the number and maximum values of the component sine waves or harmonics, which combine together to form alternating waves, whose shapes may be obtained in practice by the point by point method, employing a telephone receiver or other indicating device, or which combine to form the current waves which may be recorded by employing the oscillograph, a few of the simpler laws, governing the forming of wave shapes will be considered. If a curve having any irregular shape,
The Design and Use of the Wave-Meter

PART IV

By MORTON W. STERNs

However, the hot-wire type is the most generally used because of its lower internal resistance, which is a very important consideration in the design of the decremeter.

A very popular type of instrument on the market is the Marconi model, which is called a hot-wire wavemeter. Its scale is divided into one hundred divisions according to the square of the current flowing thru it. Its resistance is 6 ohms and it requires 80 milli-amperes for full scale deflection (0.084 watt).

In case only a direct reading milli-ammeter is available, if we make \( P = \sqrt{2} P_m \), if \( P_m \) is equal to 100, then \( P \) must be equal to 70.7 or \( \sqrt{2} \).

In part I of this series the author has listed the various measurements that can be made with a wave-meter and as can be readily seen it includes practically all the important measurements used in Radio Engineering to-day. We will now take up the various measurements in order.

MEASUREMENT OF TRANSMITTED OR RECEIVED WAVE-LENGTHS

The wave-length of a transmitter can be measured by bringing the inductance coil in proximity to the antenna lead of the transmitter and varying the condenser over the scale with the various coils in circuit to give the required range. The resonance point is the point at which the hot-wire instrument gives the maximum deflection or the point at which the lowest signal is heard in the head telephones, if a crystal detector and telephones are used. By noting this resonance point in degrees and referring to the wave-length curves furnished with the meter, the emitted wave-length can be readily found.

Figure 2 illustrates the method used in measuring transmitted wave-lengths and is familiar to all.

Figure 3 shows the wave-meter excited by a buzzer and coupled to the antenna thru a single turn.

If the receiver is tuned to the incoming signal and the coupling between the wave-meter and the single turn in the antenna lead made small, the buzzer signal will be superimposed on the incoming signals and will be weak enough so as not to interfere with the reception of messages.

The point on the wave-meter that gives the lowest signal in the receivers is then the wave-length at which the incoming message is being received.

An alternative method is to couple the wave-meter closely to the antenna circuit and when a signal is tuned in on the receiver, the wave-meter is varied until the signal dies out and becomes very weak, the minimum point being the wave-length of the received signal.

The reason the signal becomes weakened is due to the fact that the wave-meter absorbs most of the received energy at the resonance point, due to its close coupling.

II. Measurement of Decrement

In part III of this series, the method of measuring decrement with the Kolster decremeter was fully described.
ELECTRICAL EXPERIMENTER

If only a few measurements are to be made, the simplest method is to connect the standard inductor in parallel with the condenser of known value and use a unilaterial connection for the detector and 'phones.' The unilaterial connection is used so as to make the readings more accurate and to eliminate the high resistance of the detector and 'phones' around the condenser.

Fig. 4 explains the method: The wave-meter is deflected by a buzzer is brought into inductive relation with the coil under measurement. As the condenser in the wave-meter is varied the sound of the buzzer will be heard at a sharply defined resonance point in the telephones. Then noting the wave-length shown on the wave-meter and knowing the capacity in circuit B we substitute in \( \frac{\lambda}{\lambda' C} \), and find \( \lambda' \) directly by the formula, \( \lambda = \frac{3550 \times C}{\lambda} \).

If many measurements are to be made, it is best to have a permanent set-up in place around the laboratory, so that one can go right to the corner and make measurements without a lot of fuss. Some authors have a circuit like the one described in constant use and has saved much time thereby. It is a very compact arrangement and has a range of 50-300 cm.

Coil A is a long bank-wound coil tapt at various points to give continuous wave-length ranges with the two condensers C and G, see Fig. 5. The points B and C are made up as clips to clip on the coil for the various ranges, the point B always being about half-way between A and C.

A is a 0.05 m. f. condenser connected in parallel with a smaller condenser having about .0005 m. f.

The circuit L is brought near the Audion coil and the condensers C and G, varied; resonance should be found at 50°, but due to the energy withdrawn, oscillations cease at 45° when increasing capacity and at 55° when decreasing capacity in each case, causing the characteristic "kiss," and neither point being the true resonance point. If now the coupling between the two circuits is diminished, A and C will approach B as a limit and the adjustment will be so sharp that the two points A and C will be less than one degree apart on the smaller condenser, and the mean of the two readings will determine B quite accurately. It is to be noticed that the mean of inductance and capacity in the Audion circuit need not be known.

IV. Making Resonance Curves

The whole procedure of plotting a resonance curve was explained in Part II, and should be referred to by the reader, as this is a rather important measurement to be made.

V. Making Various Antenna Measurements

To measure the effective capacity of the antenna find the natural period of the antenna by exciting it with an induction coil connected across a spark gap, the side of which is grounded and the other side of which is connected to the antenna. A coil consisting of a turn or two of wire of negligible inductance is inserted in the antenna in order to allow the wave-meter to be coupled to the antenna.

When the induction coil is energized a spark will jump the gap and the antenna will oscillate at its natural period, which we will designate as \( \lambda_1 \). A known capacity, \( C_1 \), is then inserted in the ground lead and the wave-length \( \lambda_2 \) obviously smaller than \( \lambda_1 \), is measured.

Then \( C = \frac{\lambda_2^2 - \lambda_1^2}{\lambda_1^2} C_1 \)

where \( C \) is the effective capacity of the antenna in microfarads. Care must be taken that \( C_1 \) is chosen of such a value that \( \lambda_2 \) does not vary more than 20% from \( \lambda_1 \), as the effective capacity of the antenna varies somewhat with the wave-length.

Knowing the natural period of the antenna and its effective capacity, then its inductive bias can be similarly determined. Another method would be to place a known inductance in series with the antenna and measuring the wave-length \( \lambda_0 \), then knowing the natural period of the antenna, we find the inductance of the antenna from:

\[
L = \left( \frac{\lambda_0^2}{\lambda_1^2} \right) L_0
\]

where \( L_0 \) is the inductance of antenna in cms. \( L \) is Inductance of standard in cms.

VI. An Exciter Emitting Waves of Predetermined Length

Figure 7 shows how a buzzer is connected to excite a wave-meter. By setting the condenser at any value any predetermined wave can be emitted. The theory is that the inductive kick due to the breaking of

How to Make a Simple Spectroscope

By DONALD S. BINNINGTON

It is a well-known fact that when white light of any description (whether from a gas, oil or electric source) is passed through a narrow band of light, it is broken up into its component colors. On this fact is based the principle of the Spectroscope, an instrument that is considerably used in both Chemical Analysis and various experimental work. An instrument of the kind here described can be made for about one dollar and will prove a welcome addition to any experimental laboratory.

The main requirement is a prism, and the best and most efficient form is made as follows: Procure, or cut a piece of glass tubing of 1 inch bore and 1½ inches long. Break this with a glass cutter or the wards of a key, till it has the shape shown in Fig. 1. Those who do not want to make the prism can purchase one at small cost from any optical shop. Then grind the edges smooth by rubbing on a piece of emery cloth moistened with turpentine in which a little camphor has been dissolved. Finally grind on very fine emery paper until the edges are smooth and at an angle of 60 degrees (Fig. 2). Then drill a small hole in the upper side of the prism, or if the tube used is thin chemical glass tubing, the hole may be made by heating (before grinding) the side of the tube with a small blowpipe flame, with the ends corked up. The heated air in the tube having no other room for expansion will blow out a small projection, which can be filed and smoothed off. When this method is not available, the hole can be made by drilling with the broken point of a round file. When this has been done it should appear as in Fig. 2.

Now cut or procure two pieces of flat glass about 1½" x 1¼". These must be cemented on to the ends of the glass tube. The cement for this purpose is made by dissolving some glue in hot water and adding a little glycerin. Care must be taken not to smear the glue over the glass. If these directions have been followed carefully it will have the appearance shown in glass, a lens having about 12 inches or less focus. This will cost about 35 to 50 cents. Proceed to make a tube by rolling up several thicknesses of brown paper into a tube about the diameter of the lens and about 10 inches long. Make a similar paper tube to just fit into this about 6 inches long. These two tubes must be blackened inside. The black pigment is made as follows: Moisten a little lampblack with a very little kerosene and rub on to the inside of the tubes. This must not dry shiny.

The last item on the list is the slit. This is made by taking a circular piece of brass or copper, marking a line exactly across the center; filing till half thru; then carefully cut with a knife blade till the slit is just through. The length of this slit must be one-third the diameter of the lens used. This slit is shown in Fig. 5. This completes the parts. All that now remains to be done is to assemble the instrument. This is done as follows: The lens is placed in one end of the larger tube and the "slit" disc in the smaller tube. The assembled apparatus is shown in Fig. 6.

The prism is glued on to a piece of pasteboard, which is in turn glued on to the base-board, the base measuring 9" long by 4½" wide and 3½" thick. The collimating tube, as the pasteboard tubes are called, is fastened on with strips of tin. A groove is cut around the prism base to take a small pasteboard box, Fig. 7, which must be carefully blackened inside.

The apparatus is now ready for use, and an ordinary telescope or a lens placed against the spy hole will magnify the spectrum if a gas or electric light is placed in front of the slit, when a band of colors will be seen in the spy hole. If now a colorless flame is placed in front of the hole (as an alcohol lamp) no spectrum will be seen. If now a little salt (sodium chlorid) is introduced into the flame on a wire, a yellow band will be seen in the spectrum. If a potash salt is used, a violet band. If a lime (calcium) salt, a whole collection of reds and yellows and greens, is seen. Many further experiments will be found in any textbook on Chemistry or Physics.

Note: Great care must be taken to keep the carbon disulfid away from flames, as it is extremely inflammable.

[Editorial Note: A sequel article describing experiments with the spectroscope will appear in an early issue.]
A FREAK SELF-CHARGING ELECTROSCOPE.

With this piece of apparatus you can puzzle those of your friends who think they know something about electricity.

The constructional details are illustrated herewith. A brass tube of any desirable length and a glass tube that will make a snug fit inside the brass tube is required.

The glass tube is to hold the dry pile that charges the gold leaves. This is made by taking several sheets of bond paper and coating one side of each sheet with a thin coat of bronze paint and the other side with oxide of manganese. Now lay the sheets on top of each other after they have dried, all the same side up, so that a bronze side and an oxide of manganese side will always be together.

Take a leather punch that has the same inside diameter as the glass tube and with a hammer proceed to cut disks out of the several thicknesses of paper. As fast as they come thru the top of the punch they should be carefully pushed into the glass tube. Continue this until the tube is full, coating more sheets if necessary.

Now take the brass tube, solder a brass ball on one end of it, insert a wad of tinfoil in the glass tube and push it up into the brass tube. In this way contact is made between the dry pile and the brass tube.

The brass tube is now inserted into a cork and its end fitted with a small stirrup to hold the gold foil. The open end of the tube may be plugged with fiber if desired.

The trick electroscope is now complete; allow it to stand awhile and the leaves will begin to spread, indicating a charged state. Touching the ball with the finger will allow this charge to escape, but the dry pile will again charge it. The electricity is formed by the dry pile in the same manner as in the Volta pile. The bronze paint and the oxide of manganese form the electrodes of the cells and the slight amount of moisture present in the paper is the electrolyte.

These cells have a very long life and the one described will continue to charge the electroscope for several years before it needs given.

A is the brass tube; B, brass ball; D, glass tube; C, paraffined cork; F, tinfoil; G, gold leaves.

Try this instrument on some wise guy who always likes to show his superior (?) knowledge of things electrical.

Clockworks Without Gears

By THOMAS REED

SOMETHING tells me that many "Bugs" would have liked to make an electric clock as described in my articles last summer, but were discouraged by the difficulty of the wheelwork. I don't blame them. Gear movements are hard to make, there's no disguising the fact.

But I'll tell you now how to make a movement without any gears at all—without even the use of a lathe, if you haven't one, tho a lathe would make a prettier looking job.

The trick consists in substituting for the gears, plain wooden flanged pulleys, with very small rubber bands for belts.

Of course this construction couldn't possibly be used in a mechanical clock, for in those clocks the driving power is applied in a relatively large mass, by spring or weight. No belt could hold that stored power, and retail it out without slipping or undue tightness.

But in the electric clock, the power is applied at the other end of the train, in very small quantities, but constantly. So the only power or strain ever present in the wheelwork is such as one dry-cell can produce, spread over eight months; and if you'll calculate that for any given moment (in terms of electric power) you'll see that a thread-like rubber band, tight enough only to keep it straight, will easily transmit that power.

Now, then. Your first job is to find, either in your sister's workbox or a notion store, some of those smooth glass beads, the size of shot and nearly as spherical in shape that are (or were) used in fancy work.

The front and back plates of the framework as well as the posts F may be made of wood.

The outfit above described may seem unsubstantial, but I'll guarantee it to outlast the lifetime of any one of you. The rubber bands, of course, would have to be renewed every three or four years, but everything else would easily withstand such wear as it would get.

CHEMICAL "SPONTANEOUS COMBUSTION."

Purchase from your nearest drug store a small quantity of perchlorat of potash (potassium chlorate). Then powder a lump of sugar in a mortar; after which the two are mixed to the following proportions (one part of loafsugar to two parts of potassium chlorate).

Caution:—Do not mix in the mortar, but either on a paper or in a dish. When ready for the combustion, place a small quantity in a tin or old dish and add one drop of sulphuric acid (H₂SO₄). Contributed by W. DOUGLAS GELDERT.

CELLULOID CEMENT.

Hereewith is a formula for celluloid or film cement.

Formula: 4 oz. collodion 3 oz. ether 1 oz. denatured alcohol 1 oz. camphor

Mix thoroly, then add 2 feet of moving picture film that has had the emulsion removed. Contributed by GEO. W. LUCE.

GLASS-BLOWING LESSONS.

In the September number there will appear the first paper of a series by Prof. Herbert Metcalf on the art of glass-blowing. These lessons will explain every step with clear illustrations, so that you can learn the subject easily.
THREAD CUTTING

HAVING become thoroly familiar with the changing of the spindle, lead, and intermediate gears on the lathe, the student will be instructed in the present article regarding the subject of thread cutting, by taking up the successive operations necessary to cut a sharp, accurate thread.

The first and very important consideration in the cutting of a thread is to see that the object is properly secured to the live spindle and to see that the article is revolving truly on its axis. In lesson III the writer has given full particulars how to find the true center and how to secure the work to the spindle by means of a dog. This means of support is very accurate and suitable for all kinds of work.

Let us suppose the work has been secured in the lathe. The next thing is to provide the proper cutting tool and to see that its cutting edge or face is properly ground. If we are to consider the turning of an external thread, we will use the outside thread-cutting tool, Fig. 1; if an inside thread is desired, the tool in Fig. 2 is used. It will be noticed that the tools used in thread cutting are similar to the ordinary turning tool, with the exception that their points are ground to 60° "V" shape, the angle of the "V" corresponding exactly with the correct angle for the screw to be cut. There is one important difference, however, between the shape of a turning tool, i.e., that the tool point is sloped or canted at an angle. This is necessary in the screw cutting tool to prevent it from rubbing against the sides of the thread, owing to the slope or rake of the latter. The rake of a thread depends on the pitch of the screw and the diameter of the work on which it is cut; thus a screw of one-eighth pitch cut on a bolt of one inch diameter, will have a greater rake or slope than that of a thread of the same pitch cut on a bolt of two inches diameter. In other words, we must carefully consider the diameter of the stock being threaded.

In actual practice, however, it is not necessary to make a separate tool for each pitch of thread when cutting "V" threads of reasonably small pitch and diameter, the clearance angle given to the cutting edges of the tool usually being sufficient to allow for variations in the rake of the thread.

It is very essential to see that the tool is ground to the correct shape. One way is to grind it to fit between the threads of an ordinary plug-tap, but a special screw cutting gage is provided for such purposes, and it is advised that this should be in the amateur's tool kit. Fig. 3 shows how it is used and how it helps in properly setting the tool with respect to the work. Illustration in Fig. 4, shows how to set the inside thread-cutting tool with respect to the work with the use of the center or thread gage. It will be noticed that a flat steel plate "P" is laid across the end of the work "W" to form a true surface for the end of the gage to rest against.

Having carefully considered the preliminaries of this topic, we shall go into the actual cutting of threads on the object. The work being mounted between the centers and firmly secured to the face plate by means of the dog, the tool properly ground and fastened to the tool post of the slide rest, and the proper screw cutting change wheels in place, the lathe is then started and a first preliminary cut taken along the work. The tool is then withdrawn, the carriage is laid across the lever (see Lesson II) disengaged from the lead screw, the carriage is brought back to the starting point, and the tool is now set in a trifle deeper than before, the chisel being dropped into gear with the lead screw again and a second cut is taken. This series of operations is repeated until the thread is cut to a sufficient depth.

A screw-cutting tool, by reason of its shape, is weak at the point and is therefore easily broken. Consequently, the depth of cut should not be greater than the tool can easily stand, and this should be regulated in a systematic manner. A simple way is to mark with a piece of chalk the position of the cross-slide handle with which the tool is fed to the work. When the tool is withdrawn after the cut has been taken, it is wound in again before taking the next cut, so that the chalk mark is in exactly the same position as before. This shows the position of the tool during the previous cut, so that the operator can now readily judge how much further to turn the handle around to advance the tool sufficiently for the next cut. This done the old chalk mark is wiped out, and a fresh one substituted, the marking being repeated as each successive cut is taken.

Some lathes are provided with a small graduated disk on the handle of the cross feed, a fixt pointer being attached to the lathe carriage. In this case, of course, the expedients already described are unnecessary.

The second or most important precaution necessary to be observed by the novice is that the tool shall follow in the same path at each successive cut. There will be no trouble on this point when cutting any thread which is an exact multiple of the thread on the lead screw. However, if the lead screw has four threads per inch, and the screw to be cut has twelve threads per inch, the work will always be in the right position for the tool to follow in the thread when the carriage starting lever is engaged with the lead screw. It will also be true if the screw to be cut has 8, 16, 20 or any number of threads per inch which is divisible by four. This is true because the change wheel on the spindle and the change wheel on the lead screw are in exactly the same proportion to each other as the threads on the lead screw and the screw being cut.

However, to cut a thread of twelve per inch, as in the case previously mentioned, a wheel with forty teeth would be placed on the spindle and a wheel with one hundred

The External Thread Tool is Stronger than the Internal Threading Tool. It Should Have a Good Clearance and Be Accurately Ground to the Correct Angle. Self-hardening Steel is Often Used for Such Tools.
and twenty teeth on the lead screw. The spindle would therefore make three complete revolutions for each revolution of the lead screw, and the commencement of the screw thread on the work would accordingly be brought to exactly the same position in relation to the tool each time the starting carriage lever became engaged with the lead screw.

Suppose a ten thread per inch screw is desired to be cut instead of a twelve; then the wheels required would be forty on the spindle and one hundred on the lead screw. The spindle will now make only two and one half revolutions, and the work will therefore be half a revolution behind its proper position, thus causing the point of the tool to come on top of the thread instead of in the groove between the threads, if the carriage starting lever is engaged with the lead screw. If the lead screw were allowed to make half a revolution before engaging with the starting carriage lever, the work will then make another two and one-half revolutions which will bring it into the right position again for starting the tool in the proper groove. The work is therefore only in the correct position for starting a cut once during every two revolutions of the lead screw, similar to other threads which are not exact multiples of the threads of the lead screw. It will be found that to bring the tool to the right position, the starting carriage lever must only be engaged at intermediate positions of the change wheel.

In order to prevent any mistakes arising, the usual plan is to stop the lathe before the tool commences its first cut along the work, chalking a tooth on the spindle wheel and a tooth on the leading screw wheel, placing another chalk mark on the headstock opposite the former, and a chalk mark on the lathe bed opposite the latter, the starting carriage lever being then engaged with the lead screw and another cut taken. The carriage is run back to the starting point after each cut and as soon as both chalk marks on the wheels come opposite to the stationary marks again, at the same instant, the starting carriage lever may be engaged with the lead screw and another cut taken.

The writer has found from actual experience that the above troubles relative to the advancement of the tool at each starting cut can be remedied as follows: The first cut is started and ended at the proper point; then the lathe is stopt at that point. Then withdraw the tool from the work, and turn a beat mark on the tool in the opposite direction thus bringing the carriage and tool to the starting point without disengaging the carriage from the lead screw. By starting the tool at the proper cutting point and setting the point of the tool with proper reference to depth and by noting the position of the graduation on the transverse spindle the second cut is then proceeded with. This procedure is followed until the thread is cut to the proper depth. The only objection to this scheme is that it wastes considerable time by running the tool post and carriage back each time.

The above scheme of setting the carriage with respect to the lead screw and not disengaging therefrom during the completion of the thread has been found to give excellent results. It is, however, advised that the novice should become thoroughly familiar with the first as it will give considerable assistance in handling the lathe.

In cutting internal or inside threads the same methods are followed as when cutting an outside thread with the exception that an inside cutting tool is utilized and set as shown in Fig. 4. It should be remembered, however, when cutting internal threads that the diameter of the hole should be equal to the diameter at the bottom of the screw thread which is to fit into it; thus the hole intended for an inch bolt, having eight threads per inch on it, would be bored out to just under seven-eighths inch in diameter.

A very good illustration showing the various cuts and the number necessary to make a good thread is given in Fig. 5.

PHARAOH'S "SERPENT'S EGGS" TRICK.

O NE of the most amusing tricks in fireworks is the serpent's egg trick, where a little pellet when lighted, turns into a horrible snake, many, many times the size of the pellet. How awe-inspiring it is to the youngsters! Most people have no idea what terribie destruction the word allows. The explanation is simple. Mercury sulphocyanid burns with a very intense light. The little pellet is nothing more than some mercury sulphocyanid. The heat melts the ash to move off so quickly from the burning pellet that it withers and distorts itself into the shape of a miniature snake.

Lathe Set up to Cut External Threads on a Cylindrical Rod. The Stock to Be Threaded is Fastened in the Chuck and is Driven by it.

ELECTRICAL EXPERIMENTER

It requires only a little preparation and a slight knowledge of chemistry to prepare some of this compound.

Mercury nitrate (Hg (NO₃)), and ammonium sulphocyanid (or cyanid) are used in its preparation. In case these are not at hand the mercureic salt may be prepared by adding 75 c.c. of 1.2 sp. gr. nitrate to 25 c.c. metallic mercury and slowly warming till all the metal is dissolved. The excess acid should then be boiled off and the concentrated mercury salt diluted to form about a liter of solution.

The ammonia salt is prepared by adding potassium cyanid to ammeline polyphosphid, and heating slowly to dryness. (A water bath should be used if possible; if not the container holding the solution should be partly immersed in a larger container holding water so as to form a double boiler.) 25 c.c. of the KCNS (ammonium sulphocyanid) should be dissolved in 500 c.c. of water. Add 10 drops iron chloride (Fe Cl₂) to the Hg (NO₃). This will be used as an indicator. Slowly add the KCNS solution stirring constantly. A red color of Fe CNS (iron sulphocyanid) will momentarily appear but vanishes as soon as the solution is stirred. Precipitate will form. When a point is reached where the red color refuses to disappear the reaction is complete and no more of the ammonium salt need be added.

The precipitat should be filtered, washed and then about 1.5 g. dextrine dissolved in 10 c.c. of water should be added after removing the precipitat from the filter paper. The two are then thoroughly mixed and then dried for 48 hours.

When dry, the cake may be cut into little pellets of about 1/4 inch cubed. A match applied to this will produce the snakes.

Caution:—The fumes given off when burning are poisonous mercury gases and care should be taken not to inhale them. Contributed by ALBERT H. BEILER.

AMATEUR ELECTRICIANS! ATTENTION!

Did you read the prize contest article entitled "Utilizing Burnt-out Lamp Bulbs," which appeared in the April number of this journal? If not, procure a copy to-day. Here is your chance to make some money. Prizes are offered for the best ideas—"What to do with burnt-out lamp bulbs," and prizes will be awarded as follows: First prize, $3.00; second prize, $2.00, and third prize, one year's subscription to the ELECTRICAL EXPERIMENTER. Get busy, boys, and watch for the September issue.
On the Construction of Small Transformers

By Prof. F. E. Austin

As many questions are continually arising in the mind of the amateur and experimenter regarding the windings on transformers to meet certain conditions, a few fundamental principles may be explained that will enable those who so desire to either construct transformers to meet certain requirements or to remold transformers already constructed to meet new conditions of service.

Suppose a transformer has been constructed similar to the one shown in illustration, having a core one square inch in cross section, 6/4 inches long on the limbs, containing the coils and 3/4 inches on the shorter limbs. This core is made up of soft iron plates, of, say, ordinary black stove pipe iron, or even of ordinary roofing tin, which is thin iron or soft steel coated over with tin. The strips to build up the iron core are therefore 1 inch wide, and the longer strips 6/4 inches long, and the shorter ones 3/4 inches long.

If, on the other hand, the single turns were made of a band or flat ribbon of thick copper, then short-circuiting the ends of such a turn would cause a very considerable electric current, because of the very low resistance of the band and a very considerable amount of electrical energy will be supplied by the primary.

In other words, it makes no difference what the cross-section of the wire is so far as the induced pressure is concerned, but does make a difference so far as the current is concerned. So far as the load on the transformer is concerned, one turn of very large wire will produce as great a load as a large number of turns of fine wire.

It was said that the per turn pressure on the primary is very nearly the same as the per turn pressure on the secondary. Were the efficiency of the transformer 100%, meaning that just as much electrical power could be obtained from it as was supplied to it, then the per turn pressure of both primaries and secondaries would be exactly the same. If the efficiency of a transformer is 50%, then the per turn pressure of the secondary is about one-half the per turn pressure of the primary. Of course the efficiency of 50% occurs when the transformer is in operation, delivering electrical power. At no-load output, or at open-circuited secondary, the per turn pressure of the primary and secondary are the same in a well-designed transformer. When, however, the load is applied to a transformer, there is an internal pressure drop express by the resistance of the windings multiplied by the current in the windings. If the resistance of the windings does not vary in value but the current does, then the internal pressure drop will vary. As the current increases due to increased load the internal drop increases, and therefore the terminal pressure decreases.

The applied pressure is kept constant and the demanded increase in energy is supplied by the governing devices at the central station furnishing power.

For electro-welding only low pressures are required, but large currents are necessary in order to supply the necessary heat at the junctions of the two pieces of metal to be welded. A transformer for welding purposes will therefore have its secondary made of very large copper bands, and consisting of but few turns. If the same number or turns are wound on each limb or coil, then the two may be connected together in parallel, in order that the current may be doubled.

In connecting the two coils together, it will be necessary to duly regard the polarity of the terminals, as at every instant the terminals have a very positive and negative relation with each other. If two coils happen to be connected so that two positive or two negative terminals are together, the resulting pressure will be zero, provided the pressures of the coils are the same.

If the secondary winding of a transformer such as in the figure consists of two sections each having two turns, and each of No. 14 B. & S. gage copper wire, the terminal pressure of each layer will be about 5 volts at a load of about 300 watts, or a trifle less than one-half horse-power.

If copper strip about ¼ inch in width is wound on or over the secondary of No. 14 forming 2 coils of five turns each, a welding transformer will be formed, allowing, if desired, the two windings to be connected together in parallel to produce twice the current but only one-half the efficiency.

As described the transformer is a step-down transformer, stepping the applied primary pressure of 110 volts down to 5, 10, 15, 20, or 22 volts as desired by attaching to the proper terminals.

If instead of being wound with No. 14 wire, the secondary were wound with say 1040 turns of No. 28 B. & S. gage copper magnet wire, the transformer would become a step-up transformer, stepping the pressure up from 110 volts to about 200 volts.

Were a transformer capable of operating at 100% efficiency, then the pressure times the current in the secondary would be exactly equal to the pressure times the current in the primary. Then if the secondary pressure were twice the primary pressure, the secondary current would be one-half the primary current. This at once shows why such a transformer requires a small size of wire in the secondary than in the primary.

In a step-down transformer the secondary is made of much larger wire than the primary.

**Properties of Electrolytically Deposited Copper**

A preliminary report has been published of the studies of copper layers of 30 tuns on each of No. 14 B. & S. gage copper magnet wire, which transformer we have termed a step-up transformer, stepping the pressure up from 110 volts to about 200 volts.

Were a transformer capable of operating at 100% efficiency, the pressure times the current in the secondary would be exactly equal to the pressure times the current in the primary. Then if the secondary pressure were twice the primary pressure, the secondary current would be one-half the primary current. This at once shows why such a transformer requires a small size of wire in the secondary than in the primary.

In a step-down transformer the secondary is made of much larger wire than the primary.
HANFAN TAPs Holder and Cutter

The diagram herewith shows a handy friction Tape Holder and Cutter for armature winders. Without such a device one is forever hunting for the tape, besides trying to cut it with one hand.

As all of us know, there is much laying down and picking up of armature winders’ tools, and you are obliged to look all over your shop each time for the tool you want. Now this device can be clamped to the tray just where it will be the most handy and will always be found in the same place when wanted. You can pull off as much tape as you want, and then by pulling it sharply across the knife it will cut the tape. One side of the arm that hold the knife should be longer than the other and the knife set so that the tape will be cut on the bias. The knife, as you observe will do away with the handling of your shears.

As I find this a great aid to my work, I pass it on to others.

Contributed by CHARLES A. SMITH.

IMPROVED BURGLAR ALARM CIRCUIT.

In your March, 1917, number of Electrical Experimenter, on page 821 is described a “balanced burglar alarm system,” contributed by Mr. T. W. Benson, which I do not think will work very good. The contacts shown in his Figs. 1 and 2, and the battery Fig. 6, I think are all very good. The balanced relay, Fig. 3, however, will not operate exactly as described: If a “polared” ringer coil is used and the taper arm bent so that it will drop to one side, and is connected as shown in his Fig. 4, the taper will drop to one side according to the direction the current from the battery is flowing in, and stay there. I do not believe any adjustment can be made to permanently balance this relay as shown. If the permanent magnet would be removed from the ringer, the pull of the one coil would be equal to the pull of the other coil, but as the taper arm is slightly bent, when the battery circuit is closed the taper will fall in the direction it is bent, and remain there. Even if it would be possible to balance this relay, any slight vibration would cause it to drop to one side and close the contact. Another poor feature in my estimation:—When the open circuit line is closed, it will not unbalance the relay, but only allow a larger amount of current to flow thru the relay coils, due to the fact that the 20 ohm resistance is cut out of this circuit.

I submit a diagram for your consideration which I think will work better and be more reliable. As far as the contacts are concerned, Mr. Benson’s would work very satisfactory. In the closed circuit three gravity cells would be used.

The two relays are connected in series. Any style of relay having resistance of about 35 ohms would work. The armature of relay “A” is adjusted so that it will stand normally open, but will close when the open circuit contacts are closed, or if the line should be shorted. Relay “B” has a back contact, and is adjusted so that the armature is normally pulled up. When a closed circuit contact is opened or any change in the resistance of the line is made, relay “B” will open.

Relay “C” (according to my diagram) is so wired that when the contact on either relay “A” or “B” is closed, the contact on relay “C” will close and remain so, regardless of whether the contacts of relays “A” and “B” resume their normal positions. This will cause the bell to ring, or give some other alarm until switch “D” is opened.

While a separate battery is shown in the bell circuit, a connection could be made to the gravity battery to ring the bell.

A NOVEL ELECTROSTATIC EXCITER.

The little machine here illustrated is very convenient for exciting influence (static) machines and for a variety of purposes when a stream of very small sparks of either + or — electricity is required. It consists of a 3-inch length of ebonite (hard rubber) tube, A, 1/2 inches in diameter, closed at the ends, so that it can be fixed to an axle, B, of stout brass wire, passing thru holes in the center of two small pieces of varnished wood, C-C, 2½ inches long. The ends of the axle are afterward bent into handles, as shown. Two thick strips of ebonite, D D, 4½ inches long, are screwed to the wooden end pieces. A hole is made in the center of each to take a 3-inch length of brass tube, which must make a tight fit. One of these has a collecting comb, E, soldered to one end and a large brass ball, F, screwed to the other. The second tube has a similar ball, G, fixed to one end, and a fur “rubber,” H, at the opposite end. The rubber is 2½ inches long and 3/4-inch wide. It is curved, as shown at f, the degree of curvature being the same as that of the ebonite tube, and consists of a piece of any suitable fur (the writer has used moleskin, though cat-skin is best) fixed to a curved strip of brass with glue. The metal backing is, of course, previously soldered to the brass tube.

It will be understood that the rubber must press very lightly against the revolving ebonite tube, while the teeth of the collecting comb must clear the tube by about½-inch. The operation of the machine is very simple. Upon turning either handle the ebonite tube is caused to revolve against the fur-rubber. Both become electrified in consequence, the fur positively and the ebonite negatively. The capacity of the machine is, of course, very limited, and only very small charges accumulate on the metal conductors. In order to obtain a constant stream of sparks, therefore, one of the conductors must be grasped in the hand to conduct away its charge as fast as it is collected. Hold F, and positive sparks are obtained from G; hold G, and negative sparks may be taken from F, as long as the handle is turned. This is the reason for making a handle at both ends.

**WATER: History**

With the observation of Cavendish in 1761, that water was the product of the combustion of hydrogen, the ancient belief in its elementary nature was broken down. Lavoisier, in 1783, confirmed the experiment of Cavendish, and he decomposed water into its elements and conclusively demonstrated that it was composed of one part, by weight, of hydrogen, and eight parts, by weight, of oxygen. The volumetric composition was proven by Gay-Lussac in 1805 to consist of two volumes of hydrogen and one volume of oxygen.

Aside from its abundant natural occurrence, as we are accustomed to see it, water is very widely distributed in such a manner as to evade casual observation. In other words it is in places where we would be least likely to look. It is present in green plants to the extent of from 70 to 90 per cent; in fruits 80 to 95 per cent; in the animal body from 75 to 80 per cent; while the soil averaged from 5 to 20 per cent of moisture.

**Preparation.**

The simplest and most convenient method of forming this compound from its elements, i.e., hydrogen and oxygen, and proving the product to be water, is to burn a jet of hydrogen in air, and hold over the flame of a cool bell-jar, which will immediately become coated with a film of moisture. When they are mixed in the correct proportions, hydrogen and oxygen, the gas is brought in contact with a flame, a violent explosion results. If, however, they are brought together at the moment of their combustion, to prevent explosion, the mixture will burn with a very intense heat. The oxyhydrogen blowpipe is the apparatus by which this may be accomplished. Reference is hereby made to Experimental Chemistry, Fifth Lesson, October, 1916, issue of this journal, for a more complete description of the blowpipe with illustrations.

**Composition.**

Analytically, the composition of water may be demonstrated thru the electrolysis of water (acidulated with a small quantity of sulfuric acid) which when carried out by means of an eudiometer, yields three volumes of hydrogen, which collects in the arm containing the negative electrode, and one volume of oxygen in the other containing the positive electrode.

**Synthetically** the composition of water may be proven either by volume or weight. Volumetrically, by means of an eudiometer, yields exactly 1 volume of oxygen and 2 volumes of hydrogen over a column of mercury contained in an eudiometer tube (see Fig. 124). After exploring this, experiment by means of an electric spark, all the gas will have disappeared and the tube will be filled with mercury, excepting a very small quantity of water which has been formed. Should the two gases introduced be in proportions other than the above, any excess of one or the other will remain after the explosion. Gravimetrically, the quantitative synthesis of water is carried out by conducting pure dry hydrogen over a weighed quantity of heated copper oxide, the resulting water being collected and weighed. The weight of the copper oxide after the reduction is also noted. The loss in weight sustained by the copper oxide represents the oxygen consumed, and this subtracted from the water formed is the hydrogen. For example, 6.5 grams of copper oxide lost 1.31 grams of oxygen, which in turn yielded 1.475 grams of water. The hydrogen consumed would be equivalent to 1.475 / 1.31, equals 0.165 gram. Then the ratio of hydrogen to oxygen would be 0.165 to 1.31, or 1 to 7.94, which represents the combining weights of these two gases.

---

**Properties: Physical.**

Water consists in three states, i.e., solid, liquid, and gaseous (steam) within 100 degrees (C).

It freezes at 0 deg. C. and boils at 100 deg. C. at 760 mm. pressure. Under 10 atmospheres it boils at about 190 deg. Diminished pressure lowers the boiling point. The specific gravity of water at its greatest density has been selected at 1.000; at 0 deg. it is 0.99987, thus ice (0.916) floats in water.

When water crystallizes, heat is set free, while, on the other hand, when ice is fused, heat is absorbed; this is true of all fluids and solids when they pass from one state of aggregation into another. With ice or water this heat consumption or liberation amounts to 79 calories. That is, in order to fuse 1 kilo of ice, a quantity of heat will be required which is capable of raising 79 kilos of water thru one degree centigrade.

Water is the greatest solvent known. Substances dissolved in it raise its boiling point and lower its freezing point.

---

**Simple Experimental Apparatus to Be Made by the Experimentor for the Synthesis of Water.**

![Fig. 127](image-url)
This department will award the following monthly prizes: First Prize, $3.00; Second Prize, $2.00; Third Prize, $1.00.

The purpose of this department is to stimulate experimenters towards accomplishing new things with old apparatus or old material, and for the most useful, practical and original idea submitted to the Editors of this department, a monthly series of prizes will be awarded. For the best idea submitted a prize of $3.00 is awarded; for the second best idea a $2.00 prize, and for the third best price of $1.00. The article need not be very elaborate, and rough sketches are sufficient. We will make the mechanical drawings. Use only one side of sheet. Make sketches on separate sheets.

**FIRST PRIZE, $3.00**

**A MILK BOTTLE ALARM.**

A is a piece of brass cut as shown in Fig. 1, with a piece of tape or fiber (for insulation) as shown. B is a piece of spring brass cut as shown and both ends of A and B are separated by a piece of hard rubber

![Milk bottle image]

When the Milk-man Takes Your Milk Bottle from This Switch, it Closes an Electric Alarm Bell Circuit.

with tape wound around them, or else clamped together by fiber blocks. Place a bottle on the brass arm B, and as soon as anybody picks up the bottle, it causes a connection between A and B and the bell rings.

Contributed by EDWIN WOLBER.

**A SIMPLE PITH-BALL "ELECTROSCOPE."**

A simple but efficient electroscope is made as follows: A bottle made of good, clear glass and of the shape shown is necessary. A thin copper wire is bent in the shape indicated after being mounted in a tight-fitting cork. The copper wire is mounted in a poured sulfur bushing in the center of the cork. A small piece of silk thread is tied or pasted to each pith-ball and the other end is tied to the hook in the wire. When finished the pith-balls should hang two or three inches from the bottom of the bottle. Be sure the pith-balls hang exactly even in the bottle.

Contributed by MANSELL SARGENT.

**SECOND PRIZE, $2.00**

**A CIRCUIT-BREAKER FOR BATTERY CURRENTS.**

This circuit-breaker, of which a sketch is given, has proven to be very efficient. The base and uprights may be made of boxwood. The binding posts may be obtained from an old battery; the magnet can easily be made or obtained from a discarded doorbell. The dimensions may be altered but I have found the ones given very convenient. In making parts "a" and "b," care must be taken to allow for the bends at "d" and "f." The height at "d" depends on the size of the magnet; the same with the length of "a." Point "c" must fall below "a" when "a" touches the core of the magnet.

Contributed by CARL KOESTER.

**THIRD PRIZE, $1.00**

**A USEFUL HAND DRILL ATTACHMENT.**

Its principal function is to hold the hand drill straight, thus making it easier to do accurate work. Dimensions are left to be calculated by the builder to fit his particular drill. The main standard "A" must be cut in by drilling several holes in one end and then bent at an angle to fit the flat anvils on an ordinary vise. A slot may be cut in it by drilling several holes in a row, chop out with a cold chisel, and finished with files. The upper part of standard "B" is also made of 1 inch by 3/16 inch band iron, then it is bolted loosely to "a," with washers and nuts on opposite side. A clamp made of lighter material is bolted to the top to receive hand drill. To operate it is only necessary to apply pressure to top of drill.

**Tesla Current Passes Thru Glass.**

When amateur wireless stations were closed by the government, upon the entrance of the United States into the war, many operators constructed Tesla coils and resonators for use with their transformers. I am submitting a description of an experiment which requires practically no preparation, and which has a startling effect. The fact that electricity at high voltages cannot be confined by ordinary electrical insulation is well illustrated by the following experiment.

The action is as follows: When current flows thru the Tesla coil sparks leap from A and A, to the surface of the water. A steady stream of sparks also flows between D and D, at the gap G. The electricity evidently flows from A to A, thru the glasses without puncturing the glasses. If the current is allowed to flow long enough the water becomes heated.

Contributed by GEO. B. GATES. A pretty experiment, but our contributor has taken a wrong conclusion. The tumbler with water, the inside wire, as well as the outside loop forms a small Leyden jar (a condenser). Hence the easy flow of the current. However, Tesla currents easily pass thru glass.—Editor.
DRILLS MADE FROM NEEDLES.

Having occasion to use many small drills, and not wishing to incur the expense of continually replacing old ones, I used the following trick:

I procured several sewing needles of the same diameter as the drill I needed. After breaking off the eye, I ground the needle slightly flat on both sides of the large end. I then shaped the flattened end according to the sketch. These drills will do good work and will not break so easily.

REMOVING STAINS OF ALL KINDS.

Solution No. 1. 20% solution of acetic acid or tartaric acid.

Solution No. 2. Five grams of bleaching powder (Ca(ClO)). Boil in 100 cc. of water until a pink color appears. Filter and add 50 cc. of cold water.

To remove ink, coffee, tea, fruit, and dye stains, wet the spot thoroughly with No. 1. Absorb the superfluous liquid with a blotter and apply No. 2. Rinse and repeat if necessary.

For removing common stains, treat as shown in the following table:

<table>
<thead>

A WOOD SCREW WHICH CANNOT BE UNSCREWED.

Many times the experimenter has need of a wood screw which can be screwed into a piece of wood, but cannot be taken out. A screw of this kind can easily be made by taking an ordinary wood screw and filing down each side of the head, as shown in the illustration.

It will readily be seen that while it can be screwed into the wood, it cannot be unscrewed.

Contributed by G. COLEMAN.

A CHEMICAL SIPHON.

This will be especially useful to electro-chemists for siphoning off liquids from gravity batteries, etc. It is easily made by heating a glass tube till soft and drawing it out until of quite small diameter at the bend; it is bent as shown in sketch (aided by using a fish tail burner).

Its principle of operation is the "ram" action. Immersing it, keeping one finger closed over one end, and lowering horizontally into the shallow liquid. Remove finger and liquid will rush into tube, its velocity being sufficient to carry it up the narrow portion marked N, and over the bend.

Contributed by K. CLARK.

THE SYNTHETIC PRODUCTION OF RUBIES.

During the last few years, practically all of the beautiful minerals of the corundum family have been produced synthetically in the laboratory. These artificial gems are identical in beauty, hardness, and chemical composition to those obtained from the mines. The accompanying diagram shows a furnace commonly used in producing the gems.

The operations are as follows:

A trace of chrome alum is added to a solution of common alum, the chrome alum being the coloring constituent.

Then ammonia is added and a gelatinous precipitate of the hydrates of alum and chrome is formed.

This precipitate is filtered off, evaporated to dryness and calcined in a furnace at a temperature of 1000° F., into an ultimate mixture of alumina and chrome oxide. The proportion in which these two chemicals occur in the ruby are:

Alumina: 98%. Chrome Oxide: 2%.

The mixture is then ground into a powder and placed in the hopper "A." A rarely tapper which shakes the powder thru the sieve "C" into the tube "B." Thru this tube the oxygen is also supplied. Hydrogen is supplied thru the tube "E." The two gases are ignited at "F." "G" is a platform made of a highly refractory substance against which the flame strikes and on which the ruby is formed in a pear-shaped mass. The rate of flow of the powder and the temperature of the oxy-hydrogen flame must be regulated very carefully. When a bead of sufficient size has formed the heat is gradually lowered so that the gem may be free from great stresses. When it is cooled, it is broken off the base and sent to the cutter who finishes the gem.

It is important that the ingredients used in producing the minerals be of the purest obtainable.

Contributed by W. A. SCHILDKNIECHT.
Wave-Motor. (No. 1,263,041; issued to Leander W. Hammond.)

Adapted to amateur requirements in developing electric light, etc. The paddle member, which is pivoted so as to be swung back and forth by the wave action, is supported in an adjustable frame, which rises and falls with the tide, thus keeping the wave paddle at the proper height to work effectively at all times. The to-and-fro motions of the paddle cause a mechanical connected pump to force water into a tank in the manner apparent. The supply of water, which may be under pressure, in the tank on shore may be utilized for operating a wave turbine or the like, the turbine being connected to a dynamo, etc.

Electric Horn for Autos. (No. 1,264,411; issued to Henry A. Nywidler.)

A unique electric wind horn for autos and other vehicles which has a particular application to a sound-producing instrument, wherein the air currents are generated by means of a motor-driven fan. When the motor circuit is closed, it quickly accelerates the fan which draws in air through the holes opening at the rear of the fan chamber. In emerging thru the horn member the current is passed thru the musical reeds, which may be three or more in number. In this way the reeds are vibrated by the air currents passing by them.

Telegram Key Circuit-Closer. (No. 1,264,465; issued to James L. White.)

On the top of the key knob is a small lever which is normally held in such a position that the lower end of this lever permits the switch knife to close the circuit in the well-known manner. A spiral spring causes the switch knife to be normally held in the switch jaw mounted under the lower key contact. The operator when ready to send, simply pushes the switch trip to the left or against the pin on the knob, and proceeds to transmit. As soon as the knob is released, the switch closes automatically.

Talking Motion Pictures. (No. 1,265,377; issued to John M. Craig.)

He utilizes a film containing the motion pictures, and on this same film he also records the speech record in such a manner that the sound record is formed, of a substance which does not affect the transmission of ordinary white light, but which will affect the passage of rays beyond the visible rays of the spectrum. Also, the sound record on the film is made capable of transmitting ordinary white light, by being pervious to the transmission of infrared rays. The patent covers details at the rear of the battery case, either lamp can be lighted. One lamp lens gives a white light for the use of the flashlight in general illumination, and the other lens a small angle beam sharply focused for use in lighting a target.

Sound-Reproducing Diafram. (No. 1,264,215; issued to John A. Steurer.)

Diafram made, for instance, of blotting paper. This is saturated with a thin solution of a phenolic condensation product, such as bakesil or condensation, which is then dried. A circular central portion of the diafram so formed is then treated with a greater amount of the solution of such condensation product, and this part of the diafram is then permitted to dry, with the result that the central part of the diafram will absorb a much larger quantity of the sound, and consequently be much more dense. The diafram is baked to make it hard and elastic, and it has a uniform thickness, while possessing much different characteristics from an ordinary diafram of uniform density.

Heavy Current Microphone. (No. 1,263,140; issued to Lonnie Burnett Stone.)

A novel design of heavy current or high duty telephone transmitter, employing a plurality of microphonic units. These multiple microphonic units, which comprise a series of tubular chambers or shells in which carbon granules are placed, are connected in multiple with a suitable induction coil having a three-part primary winding.

Electrical Torpedo Net. (No. 1,264,820; issued to Albert Hedina.)

A net which may be used in sections, or which can be utilized separately by being arranged on a boom swinging outwards from a ship or in groups, so as to form a continuous curtain about the ship. The net is provided with a series of oppositely charged and specially insulated electrical conductors, arranged in such a manner that if a metal torpedo shell hits the net, it will cause a current to flow thru the torpedo from the oppositely charged conductors, and by virtue of the resistance offered by the passage of this current thru the shell of the torpedo, will thereby cause heat to be generated, and this heat in turn to cause an explosion of the torpedo's gun-cotton charge.
"Amateur Electrical Laboratory" Contest

In this issue we publish some interesting facts with excellent photos, describing one Amateur Electrician's experimental laboratory. Now "Bugs"—we want to publish a snappy one like it each month. Here's our proposition: Why not write up your "Electrical Lab.," in not more than 500 words. Dress it up with several good, clear photographs. If we think it good enough we will publish the article in display style and pay you well for it. The prize awarded to such articles will range from $3.00 to $10.00. And "Bugs"—don't forget to make your article interesting. Don't write—"I have a volt-meter, an ammeter, a switch-board," etc., ad infinitum. For the love of Pete put some punch in it! Tell us what you have done with your instruments and apparatus. You don't mean to tell us that every Experimenter does exactly the same thing. "We know different—but from the general run of such articles which we have received in the past, one would naturally think every "Lab." made in the same mould. Remember—send a photo of YOURSELF along. Typewritten articles preferred.

THIS MONTH'S $3.00 PRIZE WINNER—ELMER HUTCHINSON

MOST fellows do not realize the fun in having an experimental laboratory. I am in partnership with Wilbert Hartle, who lives near by. I firmly believe in partnership of two boys as one may have one thing while the other will have something else of value.

Our laboratory measures about fifteen feet by fifteen feet. We have just enough room allowing us to be purchasing and making apparatus constantly and we are usually quite crowded. The lab is located in a chemical laboratory and a desk (Fig. 1). We use the desk for correspondence, studying and drawing. In the drawers we keep magazines and catalogs. We have about three years straight of the Electrical Experimenter. Fig. 1 shows the arrangement of chemicals. We have a compound of almost every metal and salt and can therefore make any chemicals we need. I learned chemistry by having one of us mixing up something for the other to analyze.

We have a full-time stuff and countershafts ourselves and connected up the screw-cutting lathes as shown in Fig. 3. We have found this lathe very handy for turning small parts of apparatus. The small lathe (Fig. 4) is not in use at present, but as soon as we get enough time, money, and interest we will put it into use. It is used for work that is too heavy for the motor.

The pictures do not show much of the electrical apparatus among which are motors, an electric furnace, dynamo, step-up and step-down transformers, condensers, batteries, meters, etc. We have a complete "dismantled" wireless outfit.

We have many books, such as a complete set of "Hawkins Electric Guides," besides chemical, physical, drawing, astronomy and mechanical books and many I. C. S. hand-books. We learn more from our laboratory than we do from any school or book.—Elmer Hutchinson.
August, 1918

ELECTRICAL EXPERIMENTER

Phoney Patents

Under this heading are published electrical or mechanical ideas which our clever inventors, for reasons best known to themselves, have as yet not patented. We furthermore call attention to our celebrated Phoney Patent Office for the relief of all suffering daffy inventors in this country as well as for the entire universe.

We are revolutionizing the Patent business and OFFER YOU THREE DOLLARS ($3.00) FOR THE BEST PATENT. If you take your Phoney Patent to Washington, they charge you $20.00 for the initial fee and then you haven't a smell of a Patent yet. After they have allowed the Patent, you must pay another $20.00 as a final fee. That's $40.00! WE PAY YOU $3.00 and grant you a Phoney Patent in the bargain, so you save $43.00! When sending in your Phoney Patent application, be sure that it is as daffy as a lovesick bat. The daffier, the better. Simple sketches and short descriptions will help our staff of Phoney Patent Examiners to issue a Phoney Patent on your invention in a jiffy.

Prize Winner: JACKASSOMOBILE. Now that the price of gasoline has soared so high that only aeroplanes can follow its skyward rise, my new Jackassomobile will come as a boon to all gas-weary autoists. Jackass runs on endless tread in mad endeavor to eat his oats. Endless belt drives dynamo charging storage batteries. The latter, run the 60 H.P. high-speed motor which propels auto. Surplus juice feeds electric headlights, also the jackass electric spark accelerator, to urge on the Jackass, should he become a speed slacker. Inventor, Julius Lantz, Maywood, Ill.

AUTO-TROLLEY. In order to conserve our coal supply I propose to equip all trolley-cars throughout the land with spring bellows along the running-board as well as under every seat. Passengers boarding car then pump air into compressed air tank. When sitting down passengers also do likewise, and furthermore more air will be pumped into tank every time they are bounced up and down. Compressed air not only works pneumatic brakes but runs the car and the surplus power runs a dynamo which pumps juice thru trolley wire into power house. Hence power house needs no coal at all. Inventor, E. Paul Gangewere, Chattanooga, Tenn.
ELECTRIC FAN PROBLEM. (940) Arthur A. Everts Co., Dallas, Tex., inquire:
Q 1. We have a large electric fan about eight feet above the entrance to our store, directly at the door, which gives small results. This is a large four-blade fan. We realize that many customers are kept out of our store thru the necessity of opening a screen door, which we must use in conjunction with the present fan. Would one of unusual power do the work? A 1. There is only one other way that you can combat the fly nuisance, and that is by mounting several fans as shown in our diagram "A." In this manner, the fans will always blow towards the entrance and if you can arrange the fans in such a way that all the space is covered by them; in other words, that no part of the entrance is without a certain amount of draft due to the fans, then in that case we are quite certain no flies will enter.

Magnetizing Steel Bar. (941) J. C. Miller, Caney, Kan., writes the Oracle:
Q 1. That he has trouble in magnetizing a steel bar.
A 1. From your description we conceive that the trouble with your electromagnet is that it is not powerful enough to produce the results you desire. We advise using a stronger magnetizing electromagnet, and offer the following pointer in regard to magnetizing steel permanently. When the steel bar is placed over the poles of the electro-magnet, you should gently tap the steel. This is done so as to shuffle the molecules of the steel, and to cause them to set themselves all in the same direction. If you will adhere to the above, we are sure you will meet with success.

AERIAL TORPEDO. (942) Mr. A. Fiocco, Allentown, Pa., writes that:
Q 1. He has been working upon an aerial torpedo and wishes our advice on its practicability.
A 1. Relative to your Aerial Torpedo, quite possibly this may find a practical application in future military and naval operations, but at the present time, or at least to put it in another way, we would say that the efforts made by various inventors along this line, up to the present, have not been very promising.

ODD PHOTOS WANTED AT $1.00 EACH!!

Now is the time to make your Kodak pay the Hard way or way. We are after interesting photographs of out-of-the-ordinary electrical, radio and scientific subjects and are willing to pay $1.00 cash for every one we can use. Please bear in mind that for half-tone reproduction in a magazine, a photograph should be particularly sharp and clear. Of course, if a subject happens to interest us particularly well, we can have the photo retouched. For the general run of subjects, however, it does not pay to go to such expense. Therefore, please take pains to properly focus and expose your pictures. It often happens that a really mediocre subject well photographed wins approval over an excellent subject poorly photographed. And don't send us plate or film "negatives"; send unmounted or mounted "prints," preferably a light and dark one.

As to what to photograph: Well, that's hard for us to say. We leave that up to you, and every reader now has the opportunity to become a reporter of the latest things in the realm of Electricity, Radio and Science. But, please remember—it's the "odd, novel or practical stunts" that we are interested in. Every photo submitted should be accompanied by a brief description of 100 to 150 words. Give the "facts"—don't worry about the style. We'll attend to that. Enclose stamps if you desire to be returned, and place a piece of cardboard in the envelope with them to prevent mutilation. Look around your town and see what you can find that's interesting.

Address photos to—Editor "Odd Photos," ELECTRICAL EXPERIMENTER, 233 Fulton Street, New York City.

Your idea of releasing several of the aerial torpedoes so as to have them strike the water in the path of an on-coming U-boat torpedo is nothing new, as this scheme was proposed already last year by Mr. H. Gernsback. In an article in this journal was described a new form of motor-torpedo, a number of which were to be carried along on each merchant vessel. A number of inventors have worked on the scheme of aerial torpedoes to be controlled by wireless or other automatic and self-contained mechanisms, but up to this time these ideas have not proven particularly successful, so far as we are aware.

It may pay you, however, to work along the lines of a radio controlled aerial torpedo, or one that could be accurately controlled by some other means.

110 VOLT D. C. BATTERY CHARGING. (943) W. H. Jackson, New York, N. Y., asks:
Q 1. What size resistance to use in charging small storage batteries from 110 volt D. C. service.
A 1. The amount of wire for a resistance to be used directly in the 110 volt D. C. line for charging storage batteries is as follows:

Use 250 feet of No. 18 German silver resistance wire, connected as shown.

Storage Batteries Can Be Successfully Charged by Tapping off at the Proper Points Along the Resistor. Connected to a Direct-Current Circuit in This Manner.

DOES A DYNAMO "PRODUCE" ELECTRICITY. (944) Richard Bohannon, Boonville, Ind., asks:
Q 1. Does a dynamo produce electricity from D. C. service?
A 1. As to the original source of energy as developed in the dynamo, this is a rather mooted question even among the best engineers of today. It is generally considered that the dynamo does not produce electrical energy in the usual sense of the word, as the first law of physics states that energy cannot be produced—neither (Continued on page 264)
"You Get The Job"

"We've been watching you, young man. We know you're made of the stuff that wins. The man that cares enough about his future to study an I. C. S. course in his spare time is the kind we want in this company's responsible positions. You're getting your promotion on what you know, and I wish we had more like you."

The boss can't take chances. When he has a responsible job to fill, he picks a man trained to hold it. He's watching you right now, hoping you'll be ready when your opportunity comes. The thing for you to do is to start today and train yourself to do some one thing better than others. You can do it in spare time through the International Correspondence Schools. No matter where you live, if you can be reached by the mails, the I. C. S. will come to you. No matter how humble or important your present position I. C. S. training will help you go higher. No matter what your chosen work may be, some of the 280 practical I. C. S. home-study courses will suit your needs.

Choose Your Career

Do you like Electrical Work? Mechanical Engineering? Many of the foremost Electrical and Mechanical Engineers in this Country were I. C. S. trained. Civil Engineering?

Thousands of Engineers were enabled to pass their examination by the I. C. S. Civil Engineering Course. Ship Drafting? Bridge Engineering? Architecture? Chemistry?

Try! Hundreds of thousands of men have climbed into big jobs in the technical professions through I. C. S. help. Accounting? Commercial Law? All over America, Chief Clerks, Private Secretaries, Accountants, Bookkeepers, Office Managers are reaping the rewards of training gained through I. C. S. spare-time study in these subjects.

The first step these men took was to mark and mail this coupon. Make your start the same way—and make it right now.

Some Facts about the I. C. S. the World's Largest School

The first student was enrolled in the International Correspondence Schools on October 16, 1891.

Today the records of the Schools show an enrolment of over two million.

This is over six times greater than the total enrolment of Harvard in the 278 years since its organization.

It is over ten times greater than the total enrolment of Yale since its doors swung open in 1701.

It is over five times the total enrolment of all colleges, universities and technical schools in the United States combined.

Stand the members of this army equidistant and their call passed from lip to lip would send the story of the I. C. S. ringing around the world.

300 to 500 students each month report advancement or salary increases as a result of the I. C. S. training. Reports of 1,000 typical students show that at the time of enrolment their average wage was $3.00 per month. At the time they most recently reported advancement their average wage was $72.48 per month, an increase in earning power of $129.58 per month through I. C. S. Training.

What Others Have Done You Can Do

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.
THE ORACLE.

(Continued from page 262)

can it be destroyed. According to the latest theories advanced by scientists, a dynamo simply acts as a converter or transformer, if we might so call it, and gets in activity latent electrical forces which are always present in the dynamo before the armature is ever started. In other words, the field magnet of the dynamo produces a magnet field, which as we now know is one form of electricity. When the armature with its revolving wires or conductors is rotated in this magnetic field, a conversion takes place, so that electric currents are caused to develop and flow along the armature conductors. The collecting commutator mounted on the armature shaft and from which the current passes out into the external circuit thru suitable brushes.

It might be said in a broad way, that the static machine derives its electrical energy or charge from the air, but it is not correct to say that a dynamo derives its apparent energy from the air.

EFFICIENCY OF DYNAMO.

(945) Chas. A. Bazino, North Bennington, Vt., writes the Oracle.

Q. 1. In Mr. Cohen's article on the testing of small motors and dynamos, I fail to see how he obtains an efficiency of 40.2%; I figured it as 40.02.

A. 1. Relative to Mr. Samuel Cohen's article on the testing of Small Electric Motors and Dynamos" in a recent number of the ELECTRICAL EXPERIMENTER, we would advise that the efficiency in the example there cited is not quite 40.2%, and not 40.02% as your figures show. This is so for the reason that 150 watts divided by 373 watts equals a ratio of 373/150 which must be multiplied by 100 in order to give the result in per cent, and we therefore have 40.2%.

ELECTROLYTIC DECOMPOSITION OF WATER PIPES.

(946) W. W. Brinckerhoff, Mt. Vernon, N. Y., writes:

Q. 1. Can electricity destroy water pipes in the ground due to leakage currents, etc.?

A. 1. Regarding the decomposition of underground water pipes due to the effect of a considerable leakage of electric current from the railroad tracks as you mention, this is a case where currents in cities or other locations where there is liable to be any appreciable leakage of the electric current.

We would recommend that you look up this matter in any book treating on modern electric railway practise at your local library in which you will find the present practise outlined for obviating or overcoming this difficulty. In general, there should not be such an excess leakage of electric current from railroades tracks, that it will cause water or other pipes to be honeycombed and decomposed, often resulting in a dangerous condition or a break in the water main, but these cases have happened. It is generally due to a high resistance joint or a series of high resistance joints in the rails, which may be caused by the fact that they are not properly bonded at the joints between the rails. It has also been found to occur where the rails were of such electrical resistance that it could not carry properly the returned current to the power house. It is often the case that to overcome this trouble, electrical cables are run along the railway and connected to them at frequent intervals, and in this way they safely and properly conduct the retumed current to the dynamo at the central station.

EXAMINATION COUPON
Making Electrical Men To Order

Graduates of School of Engineering of Milwaukee succeed because they are prepared in accordance with the requirements of the great electrical world. They possess the necessary knowledge and practical ability to perform the functions of the Electrician, the Electrical Engineer or Experts in the various Electrical Trades. They are capable of occupying the big positions electricity affords. They obtain the recognition that befits success and the high salary ability commands.

If You Enroll Here You Are Sure To Succeed

This school, from its fourteen years’ experience and educational and industrial analysis, knows the requirements for the young man entering the great field of electricity. As a result its faculty, text books, lecture, laboratory and work-shop experiments and practice are selected to develop students to become the practical electrical men of the requirement which assures greatest success. This school is the connecting link between the ambitious young man and the high salaried, electrical positions offered. Students are instructed, trained and developed here in the way the electrical industries want them—Electrical Men are Made To Order Here. Therefore, select this school and be sure of success. Come where you know you will obtain the education you need to succeed. Save time and money—avoid mistakes. Obtain all the advantages of a required electrical education and training—all the advantages this school affords.

Decide to enroll here now—clip and mail the coupon at the left and secure new interestingly illustrated prospectus.

THE MAGNETIC STORM

(Continued from page 233)

beyond repair, a child could see that. He flung it away and went over to the next nearest flyer. But the mechanic had already located the trouble—in the motor. Burnt out, too!

You've often heard a detector utterly sick at heart, aimlessly wandering about the other machines. In each case the result was the same: Every magnet armature of the fifty flyers, each separate but the wires fused together, all insulation gone!

"Aber so was", muttered von Unterrichter, looking about him helplessly. It took fully five minutes before it filtered thru his thick Prussian skull that this disaster that overtook his "circus" could by no means be a coincidence.

"Verruchtes Amerikaner", he said, "probably a new Tesla-machine of Edison!"

But what would the Kommando say to this? Instantly he stiffened as he jumped into a waiting automobile, attached to the airarmore.

"Zum Kommando, schnell!" he ordered the driver as he sank back into his seat. He must report this queer business to head-quarters at once. The driver cranked the engine, then cranked it some more. Puf . . . puf . . . puf . . . puf . . . sputtered the engine, автоматически, but it did not start. He tried again. Same result.

One Machine for every purpose by the use of these interchangeable carriages

The ability to use any one of five different length carriages on one typewriter is only one of several exclusive features of the Fox Typewriter.

This particular feature enables an operator with one machine to do varied types of work — correspondence, billing, the making of reports, any sort of the ordinary work. The carriages can be changed in a moment, the operator doing it without the slightest trouble.

Another remarkable feature of the Fox — its extremely effortless operation — is a revelation to new users.

Fox Typewriters are used in larger numbers by Railroad telegraphers than any other type-writing machine. In no other class of work do typewriters receive harder use, and the ability of the Fox to stand up year in and year out under such trying conditions has put it in first place with these discriminating users.

The Fox dealer in your locality will be glad to place a machine on trial in your office. Should it happen that there is no dealer in your immediate vicinity, write us direct and we will make it easy for you to test out the Fox in your own office.

"Donnerwetter nochmal!" stormed the Baron. "Slow over the delay "was it done — jetzt los, why in thunder don't you start, you miserable dog?" But the engine would not start. The perplexed chauffeur climbed into the seat of the old style car, which still had its faithful spark coils, so necessary to the ignition system. But the spark coil refused to work, altho the storage battery was fully charged and all the connections were right. Caustiously he pulled out one of the spark coil units from its box. Once again he sought the story.

"Augezgrubent, Herr Leutnant," he said weakly, for he had seen the burnt out magneto armatures a few minutes before.

Von Unterrichter, with eyes almost popping out of his head, was struck absolutely speechless for half a minute. "Heiliger Strohsack!" he muttered, his gaze stricken, remembering his young sister's favorite expression, whenever something out of the ordinary happened. They rapidly collected himself sufficiently and jumped out of the car.

"Zum Telefon!" he muttered to himself. He must report this uncanny occurrence at once to the Kommandeur. Not a second was to be lost. He at last understood that something momentous had happened. He made the airdrome on the run and tho it was only 200 yards away he surprised himself at the speed he made. Puffing volubly he arrived at the telephone. He gave the handle several quick turns, grasped the receiver and simultaneously hollowed into the mouthpiece in front of him:

"Hallo, hallo" . . . but he went no further. The receiver flew from his ear, for there had been a loud clattering, rattling, ear-splitting noise in the instrument that almost burst his eardrum. He made a foolish grimace, as he held his ear with his hand. Caustically he approached the receiver to within a few inches of his other ear and listened. All was quiet, not a sound. Mechanically he unscrewed the receiver cap and looked at the two bobbins. They were charred and black. The telephone was dead . . . .

The instrument slipped from his hand and dangling by its red and purple cord went crashing against the wall of the airdrome, while von Unterrichter limply sank into a chair.

Once more he got up and walked out. He might get into trouble with his General at all costs. This was becoming too serious. Ah . . . he had it, the field telegraph. There was one at the other end of the building. He went there as fast as his legs could carry him. He opened the door of the little office but one look sufficed. The young man in charge of the telegraph sat in a corner, a dumb expression in his eyes. Long purple sparks were playing about the instruments on the table. A child might have seen that it was impossible to either send or receive a telegram under such conditions. . . . Ah! an inspiration.

"Dummkopf!" he muttered to himself. "Why didn't I think of it before. Die Funkenstation! Surely the wireless must work! Ha, ha, there are no wires there at least to burn out!"

The radio station was over a kilometer away. He knew it well, for he had flown over it a great many times. To get there quick, that was the question. The Kommandeur had at least eight kilometers to the rear, and he knew he could not make that distance on foot very quickly. Ah, yes, there was a horse somewhere around. The

Century
man
flung
back
a
hundred
yards.
He
screamed
into
the
distant
railroad
embankment
struck
his
eye.
No
train
was
moving.
Everything
was
at
a
standstill—how
could
a
train
move
with
ten
cars
stuck?
How
could
a
train
be
dispatched—there
would
be
a
thousand
collisions.
He
turned
to
the
radio
operator,
who
as
yet
had
not
grasped
the
situation
in
its
wholeness.

ELECTRICAL EXPERIMENTER

“Nördlich, nicht wahr, Herr Leutnant?” he began, thinking no doubt that the phenomenon was an ordinary form of Aurora Borealis,—the northern lights,—in other words, a magnetic storm, that would be soon over.

“Dumme Rindsviech!”... snapp the Herr Leutnant, who knew better than this. Indeed he was to know still more at once, for while he was speaking there came to his ear a noise of hammering, as if he had heard it once before, way back in 1914 when the Germans had retreated very much in a hurry beyond the Marne.

Paradoxically, though the sound was unmistakable. The German army once more was in full retreat—no it was a panic-stricken rabble that made its way back.

Like lightning the news had spread among the men at the front that uncanny things were afoot, that all communications had been cut, and that announcements of that order could be sent or received except by prehistoric couriers, that the Groesse Kampf was cut off from the army, and that in short the German army as far as communication was concerned, had suddenly found itself a century back.

For what had happened to von Unterrecht, and his band of seven, based on a large scale not only to every one along the front, but all over Germany as well! Every train, every trolly car, every electric motor and every domestic and telegraph had been put out of commission. With one stroke Germany had been flung back into the days of Napoleon. Every modern innovation,— except horse-drawn vehicles,— were at a standstill. For days the German retirement went on, till on the fifteenth day, the entire German army had retreated behind the natural defenses of the Rhine, the victorious Allies, pressing the feeble hordes back irresistibly.

And it must have been a bitter pill for the German high command to swallow when they saw that the Allied airmen were constantly flying behind their own lines and that all their airmen were without the automobiles and their trains seemed to run as well as ever behind their own lines. But no German succeeded in flying an aeroplane or in running an automobile. That mysterious force obviously was trained only against the Huns, but was harmless behind the Allied lines. The huns had flown too far out to date what caused their undoing.

Peace having not been declared as yet, I cannot, of course, divulge the full details of the reason of just how the Germans were finally flung across the Rhine. That, of course, is a military secret.

But I am permitted to give an outline of just what happened on that memorable morning, when the German “Kultur” was flung back into the dark ages where it belonged.

But first we must go back to Tesla's laboratory once more, back to that evening when “Why?” Sparks first overwhelmed Tesla and his companions with his idea. This is the part which the sparks said.

“Mr. Tesla! In 1898 while you were making your now historic high-frequency experiments in Colorado with your 300-kilocycle generator, why you were quite shown the obscure secret of the dynamo and its apparatus, which you, without knowing it, were the first to tell, and which you were in the service of writing on such a way, it appears to be now a thing quite as much as ever before the same.

Have you an idea what the Tesla was, a Patrician of the War Zone? If so, you may be of some value in doing this work. Ask for a Free Copy of our new booklet entitled "Handbook of the Tesla High Frequency Oscillator," to receive new patents, courses and advance course, most valuable information of the field, and you will have it at your sale. This book is the indispensable companion of the Tesla High Frequency Oscillator.

THE ELECTRICAL EXPERIMENTER

This book cost $28,000
Over 1200 Authors Contributed

Contains a goldmine of electrical and scientific information. No such value has ever been offered before for so low a price. A magnificent encyclopedia of electricity. A reference book of authentic information and found in all leading electrical libraries. Valuable to all electrical engineers and students. 1,100 pages, 13,000 illustrations and answers. Size: 12 x High: 8 wide: Fig. thick.

$2.00
Add 50c postage for illus.

EXPERIMENTER PUB., Co., Inc., 233 Fulton St., New York, N. Y.
so we place a huge 3,000 kilowatt generating plant with its necessary spark gaps, condensers, etc. The feed wires from these generating plants then run into the thick wires, strung along the telegraph poles, forming the gigantic Tesla Primary Coil. Of course, you realize that in a scheme of this kind it is not necessary to run the telegraph poles actually parallel with every curve of the actual front. That would be a waste of material. But we will build our line along a huge flat curve which will sometimes come to within one-half mile of the front, and sometimes it will be as much as fifteen miles behind it. The total length of the line I estimate to be about 400 miles. That gives us 40 generating plants or a total power of 120,000 kilowatts. A parallel line is built along the Italian front, which is roughly one hundred miles long at present. That gives us another 30,000 kilowatts, bringing the total to 150,000! Now, the important part is to project the resultant force from this huge Tesla primary coil in one direction only, namely the same front. We can easily do that by using certain condenser coils. This I can find can be readily accomplished by screening the wires on the telegraph poles at the siding facing our way as well as by using certain condenser coils. The screen is nothing else but ordinary thin wire netting fastened on a support wire between the telegraph poles. The screen then acts as a sort of electric reflector. So. . . . Sparks demonstrated by means of one of his sketches.}

"Everything completed we turn on the high-frequency current into our line from the sea to little Switzerland. Immediately we shoot billions of volts over Germany and Austria, penetrating every corner of the Central empires. Every closed coil of wire through Germany and Austria, be it a dynamo armature, or a telephone receiver coil, will be burnt out, due to the terrific electromotive force set up inductively to our primary current. In other words every piece of electrical apparatus or machinery will become the secondary of our Tesla coil, no matter where located. Moreover the current is to be turned on in the day time only. It is switched off during the night. The night is made use of to advance the telegraph poles over the recaptured land,—new ones can be used with their huge primary coil wires, for I anticipate that the enemy will never fall back. Turning off the power does not work to our disadvantage, for if it is suitable to suppose that the Teutons will be able to withstand all our new coils and armatures to replace the millions that were burnt out during the day. Such a thing is impossible. Besides, once we get the German mind moving, it ought to be a simple matter to follow up our advantage, for you must not forget that we will destroy ALL their electrical communication. No aeroplane, with automobile, will move through the Central States. In other words, we will create a titanic artificial Magnetic Storm such as the world has never seen. But its effect will be vastly greater and more disastrous than any natural magnetic storm that ever visited this earth. Nor can the Germans safeguard themselves against this electric storm any more than our telegraph companies can when a real magnetic storm sweeps over the earth. Also, every German telegraph or telegraph line in occupied France and Belgium will be our ally! These insulated metallic wires actually help us to "guide" our energy into the very heart of the enemy's countries. The more lines, the better for us, because all lines act as feed wires for our high frequency electrical torrents. . . .

MAGNETIC RECTIFIER PATD APR. 18, 1915

You Need This Useful Tool
The "RED DEVIL" Chain Drill will drill engine cylinders, sheet steel, steel beams, wagon tires, safes, boilers, pipes, flanges, etc. It can be used as a clamp. Works with a bit-brace, hand-drill, breast-drill or even a wrench.

The "RED DEVIL" Chain Drill
has an automatic feed, adjustable to any pressure. It is practically a portable drill-press. Friction minimized by hardened tool-steel ball bearings and ball races. Thread is machine-cut from the solid rod, not cast. Has 6 ft. polished steel chain, extra length if required. Nickel-plated Universal Chuck holds round or square shank drills and bits 3/16" to 3/8". Alligator jaws of forged tool-steel.

If not at dealer's, send his name and $2.45, and we'll see you are supplied.

Ask your dealer to show you other "RED DEVIL" Tools: Pliers, Hack-Saws and Blades, Glass-Cutters, Electrical Tools, etc.

SMITH & HEMENWAY CO., Inc., 107 Coit St., Irvington, N. J.

A few kilometers north of Nancy, in the Department of Meurthe et Moselle, there is a little town by the name of Poincaré. It is a progressive, thrifty little French town of chief importance principally for the reason that here for four years during the great war the French army had been quartered to the German frontier than at any other point, with the exception of that small portion of Artois actually in the hands of the French.

Nomeny in the military sense is in the Toul Sector, which sector early in 1918 was taken over by the Americans. If you happened to go up in a captive balloon near Nomeny you could see the spires of the Cathedral of Metz, the great French fortress, but 16 kilometers away, always presuming that the air was clear and you had a good glass.

On a recent warm summer morning there were queues doings at a certain point in the outskirts of Nomeny. All of a sudden point seemed to have become the center of interest of the entire French, British and American armies. Since dawn the military autos of numerous high Allied officers had been arriving while the gray-blue uniforms of the French officers were forever mixing with the business-like khaki of the British and Americans.

The visitors first gave their attention to the camouflaged, odd-looking telegraph poles which looked to me like whale bones. It was with the difference that the many wires were running horizontally, the telegraph line stretching from one end of the town to the other. A few hundred yards back of this line there was an old brewery from which ran twenty thick wires, connecting the brewery with the French officers' hotel. This brewery the high officers next strolled.

An inspection here revealed a ponderous 3,000 kilowatt generator purring almost silently. On its shining brass plate the legend: "Made in U. S. A." There was also a huge wheel with large queer, round pieces. Attached to the axis of this wheel was a big electric motor, but it was not running now. There were also dozens of huge glass jars on wooden racks lined against the wall. Ponderous copper cables connected the jars with the huge wheel.

One of the French officers, who prior to the war had been an enthusiastic Wireless Amateur, was most interested in this huge wheel and the large glass bottles. "Aha!" said he, turning to his questioning^ "Can't you read the inscription on the glass bottles?" ""Eclateur rotatif et les bouteilles de Ledye."

There was little satisfaction in this, but just then a red-haired, tousel young man seemed to be busy, seeming to be the man in charge, came over and adjusted something on the huge wheel.

"What do you call all of these do-"furnaces?" our young officer inquired of him, pointing at the mysterious objects.

"Rotary spark gap and Leyden jars," was the laconic reply. The officer nodded. Just then an auto came through the gate.

President Poincaré was introduced to the red-haired, tousel young man whom he address as Monstre Sparks. Monstre Sparks speaking a much dilapidated French that was of no great help in his excellence all of the important ma-

"Le Président de la République!" instantly every man stood erect at attention. A few seconds later and President Poincaré walked in slowly, at his side General Pétain. It was then five minutes to 10.

President Poincaré was introduced to the red-haired, tousel young man whom he address as Monstre Sparks. Monstre Sparks speaking a much dilapidated French that was of no great help in his excellence all of the important ma-

"Monstre Poincaré was much impressed and visibly moved, when a French officer had gone over Sparks' ground, and re-explained the finer details.
The President now takes his stand on an electric switch which has an ebonite handle about a foot long. He then addresses the distinguished assembly with a short speech, all the while watching a dapper young French officer standing near him, with a chronometer in hand.

Somewhere a clock begins striking the hour of ten. The President still speaks but hesitates a few seconds later. The distinguished assembly applauds and cheers vociferously, only to be stopped by the dapper young officer who slowly raises his right hand and points to the chronometer. Immediate silence prevails, only interrupted by the soft purring of the huge generator. The dapper young officer suddenly sings out:

"Monsieur le President! A-ten-tion! ALLEZ!"

The President of the glorious French Republic then shouts dramatically: "Messieurs . . . le jour de gloire est arrive . . . VIVE—LA FRANCE!"—and throws it in the huge switch with its long ebonite handle.

Instantly the ponderous rotary spark gap begins to revolve with a dizzying speed, while blinding blue-white sparks crash all along the table in front of the President, like a hundred cannons set off at once. The large and electric hall intensifies the ear-splitting racket so much that every one is compelled to lean over the tables with what seems like their lives.

Quickly stepping outside the party arrives just in time to see fifteen Boche aeroplanes, volplaning down and disappearing behind the walls of the French capital. The dapper French officer who had observed the German aeroplanes, drops his glass, steps over to the President, salutes him impressively:

"Le 'cercue' du Baron d'Unterrichter! Ils sont hors de combat!"

Hors de combat is correct. Von Unterrichter was not to fly again for many a week.

We look around to tell the glad news to General Pétain, but the latter has disappeared into a low brick building where he now sits surrounded by his large force poring over maps ornamented with every kind of vari-colored pencil marks, as well as little brightly-colored pin flags. Telephone and telegraph instruments are all about the room.

Again the President shakes hands with Monsieur Sparks, congratulating him on his achievement. Luncheon is then served in the former office of the government, greatly bedecked with the Allied flags along the walls. But even here, far from the Titanic rotary spark gap, its crashing rapids is quite audible. Looking thru the window we see a wonderful sight. Altho it is broad day, the entire queere telegraph line is entirely enveloped in a huge violet spray of electric sparks. It is as if "heat-lightning" were playing continuously about the whole line, making the electric venture within fifty feet of the line. It would mean instant death by this man-made lightning.

Luncheon is soon over and more speeches are made. Suddenly the door flings open and a herald in Paris looms up. One look at his remarkable features, and all talk stops as if by magic. He crosses the room to the President, salutes and says in a calm voice, the echo of his dry impact is from the President:

"Monsieur le President, toute l'armée Allemande est en retraite!"

And the President, with the greatest and final retreat of the Kaiser's "inviolable" hordes was in full swing towards the Rhine.

More congratulations are to be offered to Sparks. A medal . . . Heavens, where is that young man? But Sparks has over to his machines and is standing in front of the noisy "thunder and lightning" wheel eyeing it enthusiastically.

"Why, oh WHY, do they call you éclateur!" he says. "Spark Gap is good enough for me!" "Oh, boy! But you aren't doing a thing to those Germs!"

THE END

---

**ELECTRICAL EXPERIMENTER**

**GERMAN**

Verdammt Yankee Schweiemerden: Damned Yankee Pig-Downs.

So, Muller: You, Muller! 20 Befehle, Kamerad. At your orders, Lieu-

tenant!

Vorsammlung, sofort: Assembly, at once!

Dieses Amerikanische Gesindel: This American rabble!

Schließt die Lappen zusammen: Shoot the rag-

Vormündern für Gott-und Vaterland: Onward, for God and Fatherland.

Dollargeld: Dollar Chasers.

Eльndliche Schweiemerden: Miserable hand of pigs.

Fliegen: Flyer (aeroplane).

Himmelskreuzdonnerwetter: A popular German cuss word. Literally it means "skye-cross

thunders.

German equivalent is "A thousand

thunder.

Kopf: German slang, equivalent to our slang "busted.

Auseinanderausnahme: Take it apart!

Ausgestreckt: Bambirn.

Aber so was: Such a thing (of all things).

Vergeblich Amerikanische: Useless Americans.

Teufelsmaschine: Diabolische machine.

Zum Kommando, Geronimo, to Headquarters.

Dammerronnetz: By all thunders!

Was ist denn das: What's up now?

Heiliger Stroklupfer: Holy hag-straw, equivalent to "Holy Gee."

Dammklopfe: Blocked.

Die Punktstation: The Radio Station.

Gott sei Lob: Praise be to God.

Aber, Herr Leutnant: But, Lieutenant!

Man hat die Karten: One has the cards.

Lächeln denkenst: Quenched Spark Gap.

Khals! (wichtig): Not? Northern lights, it is not.

Dummner Rindsback: Stupid piece of cattle.

Grosse Kommando: Headquarters.

**FRENCH**

L'electricien rotatif et les bottes de Lézard: Ro-

tary spark gap and Lizard shoes.

Le President de la République: The President of the Republic.

Monsieur le President! Attention! Allé! Mr. President: Attention! Forward!

Messieurs, le jour de gloire est arrive, voie à la France! Drums begin to roll, and glory has arrived, long live France! (This is from the second verse of the "Marseillaise")

Le cercue du Baron d'Unterrichter. Ils sont hors de combat: Baron von Unterrichter's cir-

cul: They are out of the fighting!

Monsieur le President, l'armée Allemande est en retraite: Mr. President, the entire Ger-

mam army is in retreat.

**EXPERIMENTAL CHEMISTRY.**

(Continued from page 256)

Thus the most striking examples are certain electro-positive oxides, as Potassium Oxid (K₂O) and Calcium Oxid (CaO).

CaO + H₂O = Ca(OH)₂

With the oxides of certain electro-negative it combines energetically to form acids.

H₂O + H₂O = H₂SO₄

these reactions being strongly exothermic.

Under certain conditions the halogens (Cl, Br, F) will dissolve some water with the liberation of oxygen, which in turn acts as an oxidizer, while the hydrogen forms a haloid acid.

Cl₂ + 2H₂O = 4HCl + O₂

Natural Waters. These include all such waters as occur naturally upon the surface of the earth which are more or less im-

pure from the presence of dissolved gases and numerous inorganic substances. These waters may be class as rain, spring, mineral and sea waters.

Rain water is the purest form of natural water, but it frequently contains such gases...
as carbon dioxide, ammonia, sulfuric oxidz and nitric acid, salts derived from these are transparent and also conans small quantities of foreign matter which are present in the atmosphere and which are carried down by the rain drop.

Spring water is usually found to hold

salts in solution. The water supply of

cities is usually taken from lakes or rivers which are supped from the mountains, streams, and springs. These waters contain chiefly the carbonates and sulfates of calcium and magnesium, with small quantities of the alkalies, iron, silica, and organic matter, which may be either living or dead. Hard and Soft waters. For domestic or manufacturing use the chief factor which determines the value of the water is its hard-

ness. This hardness is due to the presence of calcium and magnesium salts, which form insoluble precipitates the sample of results in the latter failing to cleanse until these salts have been completely precipitated. When employed for feeding boilers hard waters form a more or less coherent deposit, commonly called boiler scale, which causes clogging and frequent burning out of the tubes. Usually the rhodium or calcium phos-

phate and sulfate of calcium with some iron oxid and silica.

Hard water is of two kinds, temporary hardness and permanent hardness. Temporary hardness is caused by the presence of the bicarbonates of calcium and magnesium, which may be removed by boiling, whereby the bicarbonate which has held the insoluble carbonates in solution, passes off and the precipitation ensues. Thus

\[ Ca(HCO_3)^+ + \text{Heat} \rightarrow CaCO_3 + H_2O + CO_2 \]

This temporary hardness may also be removed by the addition of alkali carbonates or hydroxides.

\[ Ca(HCO_3)^+ + \text{NaOH} \rightarrow CaCO_3 + 2H_2O \]

Permanent hardness. Permanent hard waters contain the sulfates or chlorides of magnesium and calcium, or both. Thus we may account for the more or less hardness of water after boiling. These may be removed through the addition of soluble carbonates, as, for instance, Sodium Carbonate or Ammonium Carbonate, whereby the calcium or magnesium precipitate as carbonates. The soluble alkali sulfates which remain in the water is a serious action when the water is used for boilers.

\[ CaSO_4 + Na_2CO_3 \rightarrow CaCO_3 + Na_2SO_4 \]

Water is said to have a certain degree of hard-

ness when it contains one part of calcium carbonate or its equivalent in one hundred thousand degree of hardness is determined by agitating a certain volume of the water with a standard solution of soap until a permanent lather is produced.

Purification of Waters. Water Supply is one of the most difficult questions confronting Mankind, especially in large cities. Ancient Rome brought her water in great aqueducts, since the Roman time, from the Apennine Mountains, forty or fifty miles away. Lake Michigan is the source of Chicago's supply. Boston has constructed a series of artificial lakes in the center of Massachusetts. These lakes are fed by water from surrounding streams. Waters from such sources cannot be pure. They contain (1) dissolved salts; (2) suspended matter; (3) Microorganisms which are usually harmless, but which may be and sometimes are the germ of disease. Epidemics of typhoid and scarlet fevers have often resulted from drinking such water. Most large city water supplies are now puri-

fied by removing impurities or water over filter beds made of gravel, laid to the depth of several feet (see Fig. 125). After flowing thru the filter beds the germs are found to be mostly removed and the water is collected in reservoirs, whence it runs in pipes to consumers. After using one bed a short time the water is turned on to an-

other, and the first bed is dried in the sunlight, destroying the germs.

Even after thus filtering, the water is hardly pure enough for drinking. It may be treated in one of three ways: (1) Boil-

ing the water for some time destroys organic life, both animal and vegetable, including microbes, thus rendering it harmless toward all volatile gases. (2) It may be filtered by forcing it thru a Pasteur or similar filter made of porcelain. (3) Distilled water is the purest. Distillation leaves behind any dissolved salts, but it does not remove gases or even liquids whose boiling point is as low as that of water (e.g. 212 F. — 100 C.). This process does not take out any dissolved salts, but these are comparatively harmless. It does remove any suspended matter, in-
cluding germs, thus making the water pure and colorless. This is the usual pro-

cess for purifying drinking water.

CHEMICAL TESTS OF WATER

Experiment No. 139.

Free Ammonia. Nessler's Test. To determine such minute quantities as 0.0025 we make use of Nessler's Solution, an alkaline solution of mercuric iodid, in potassium iodid. When a few drops of it are added to a dilute solu-

tion of ammonia or of an ammonium salt, it forms a deep red precipitate, which, even in very small amounts, is a yellow or brownish tinge to water. Thus

\[ 2HgI_2 + NH_3 \rightarrow NH_2I + 3HI \]

This precipitate, which may be considered as ammonium iodid, with two mercury atoms in place of four atoms of hydrogen, is excreted by the kidneys of heavy, for example, if alcohol was mixed with water, it would dis-

till before the bulk of the water, but would not be separated, as it boils 22 degrees lower than water. This condensate is usually employed in the laboratory for dis-

tilling water.

Nitrates. After the nitrogenous matter has been sufficiently decomposed to liberate ammonia and other similar gases, so-called nitrifying ferments, begin to oxidize this ammonia, first into nitrates and finally into nitrites. This, however, is not as delicate as Nessler's reaction; and, as the nitrates are probably a transition stage in the oxida-

tion of nitrogenous matter, it is rather rare to get a good test in perfectly pure water. For this reason, probably the significance of their presence has frequently been greater than the fact.

The reaction is based upon the formation of a scarlet coloring matter, one of the "azo" dye stuffs, by the action of nitric acid upon two aminoic or organic bases. The test is interesting as between a counterpart of the well known Ehrlich's reaction and where the nitrous and sulfanilic acids are mixed together and the compound corre-

sponding to the naphthylamine salt is fur-

nished by the urine.

Boys! There's No End of Fun to Be Had With CHEMCRAFT

THE BOY'S CHEMISTRY OUTFIT

You can work dozens of wonderful experiments in chemistry and Chemcraft Magic. You can satisfy and entertain your friends by the boy is asking and adding knowledge to edge of chemistry that will be of greatest use to you all your life.

Just think of being able to make wonderful changes such as you have seen magicians perform — and you can manufacture useful things too — links that you can write with — soap — fireworks — and lots of others.

CHEMCRAFT IS MADE IN THREE SIZES

No. 1 sells for $1.25

West of the Mississippi and Canada, $1.50

No. 2 sells for $2.50

West of the Mississippi and Canada, $3.00

No. 3 sells for $5.00

West of the Mississippi and Canada, $5.00

Write for further information and name of dealer who sells Chemcraft.

thoroughly taught at

Y. M. C. A.

TELEGRAPH SCHOOL

Maze Ave., near Broadway, BROOKLYN
Fill two large test tubes respectively with Croton and with water. To each add a few drops of the saturated solutions of sulfanilic acid, and of naphthylamin hydrochlorat. A pink or red coloration appearing shows the presence of nitrates.

Notice the Croton water does not turn pink until it has stood for some time, and has absorbed some nitrates from the air.

Experiment No. 141.

Nitrates

We can test for these substances in two ways, either by reducing them to ammonia and using Nessler's solution, or else by directly producing a colored compound.

(a) Reduction Method. The best reducing agent is certain hydrogen, which can be evolved in the water to be tested, by dissolving aluminum in an alkali (as Sodium Aluminate).

\[ \text{Al}_3^+ + 2 \text{KOH} + 3 \text{H}_2 = 2 \text{KAlO}_2 + 3 \text{H}_2 \]

or else by the action of the water upon two different metals, such as zinc and copper. When these two, in close contact, are immersed in water, a true galeenic couple is formed, and oxide zinc is oxidized, and hydrogen is set free from the negative copper. This hydrogen slowly converts the nitrates first into nitrates and finally into ammonia, according to the following equations:

\[ \text{NaNO}_3 + \text{H}_2 = \text{NaNO}_2 + \text{H}_2\text{O} \]

\[ \text{H}_2\text{SO}_4 + \text{NaOH} = \text{NaHSO}_4 + \text{H}_2\text{O} \]

This ammonia can be accurately determined by Nessler's Test, and the quantity of nitrates calculated accordingly.

(b) Phenol-Sulfonic Acid Test. We can estimate the quantity of nitrates directly by noticing the depth of color which they produce in a solution of phenol in strong sulfuric acid. The reactions being:

\[ \text{C}_6\text{H}_5\text{OH} + \text{H}_2\text{SO}_4 = \text{C}_6\text{H}_5\text{OHSO}_3^+ + \text{H}_2\text{O} \]

and then in the presence of traces of nitric acid or nitrates.

\[ \text{C}_6\text{H}_5\text{OHSO}_3^+ + \text{HNO}_3 = \text{C}_6\text{H}_5\text{O}_2\text{NO}_2 + \text{H}_2\text{O} \]

The color is intensified by the addition of an excess of alkali.

(a) Reduction Method Experiments. Clean the zinc in a wide-mouth bottle by adding some water and a little dilute hydrochloric acid, permitting it to effervesce for a minute or two, and then rinse out thoroughly. After this, cover with water, add three or four drops of copper sulfate, and let stand for a few minutes until the zinc is fairly covered with a black deposit of metallic copper. Then rinse it out well, and fill the bottle with Croton water.

Test the reducing action of this "zinc-copper couple" on nitrates by adding two or three crystals of sodium nitrat to the water in the bottle, shaking it till they dissolve, and then letting it stand quietly until the end of the hour. Notice the slow but continuous evolution of hydrogen, and before leaving, test the solution for nitrates and free ammonia, as previously described.

(b) Phenol-Sulfonic Acid Test Experiment. Add one or two drops of sodium carbonate to 30 cc. of the well-water, and evaporate the mixture to dryness in an evaporating dish. This can be done at first over the flame, but must be finished over the water-bath. Cover the residue with a solution of phenol-sulfonic acid, made by dissolving, carefully, in a test tube, a few drops of phenol with twenty times its bulk of common sulfuric acid. Then add about 19 cc. of Croton water and an excess of potassium hydroxid. If nitrates are present in the well-water, the mixture will have a yellow or even an orange color.

(To be continued.)

High Frequency Bargains

In taking our inventory we found over 200 Violet-Ray machines of all makes. We selected 100 of the best machines, which we thoroughly overhauled in our factory making them better than new. Many of these machines cost over $40.00.

We have placed all these instruments in two groups and are disposing of them for the ridiculously low price of $9.75 and $12.50.

How to secure one of these machines

Send only 50 cents to pay express charges and we shall send you one of these instruments by express for your examination. This amount will be deducted from the total cost of machine. You need not accept if not satisfactory.

Send at once for we shall send the best machines out first and the quicker you send in your order, the better machine you will get.

We shall also send our beautiful booklet "Violetta" describing the many uses for the high-frequency current. Write us before purchasing any kind of Violet-Ray Machine.

"EXPERIMENTS" $1.50
By P. Edelman

Studies some ancient books like this magazine dedicates itself to the technical. The one which we have is the "Electrical Experimenter," which is published monthly. The book is divided into sections: Electrical, Mechanical, Chemical, Medical, and others. Each section contains articles on various topics related to technology.

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.
BUZZER OPERATION TAUGHT IN 600 SCHOOLS

The demand for specialists in the Army is increasing daily. Mechanics and technicians of all kinds, including radio and buzzer operators, are needed by the Signal Corps.

In nearly every large city the Federal Board of Vocational Training, thru local school authorities, has established schools of Radio-communication where men of draft age who have not been called may receive a preliminary course in the operation of radio and buzzer instruments. There are about 600 of these schools where instruction is given, usually in the afternoons and evenings. It takes about 200 hours for a student of average ability to obtain a speed of 20 words a minute, sending and receiving. Further information regarding schools may be secured from local school authorities.

DE FOREST WIRELESS SUIT

The trial of the patent infringement suit brought by the Marcon Wireless Telegraph Company against the De Forest Radio Telephone and Telegraph Company, which was to have commenced on June 12th, in the New York District Court, was, at the request of the Navy Department, suspended by Judge Mayer for the duration of the war.
remedies this fault. From this it will be seen that the main driven shaft is connected to a differential and the energy transmitted through regulator to the motor. When the energy developed by the wheel, the excess energy is used to wind up a weight. The wind is not a constant source of energy, and even when there is no work to perform, it is often noticed the wheel will stop for a few seconds. When a small weight descends and a ratchet prevents the shaft revering from the engine, the differential and keeps the generator up to normal speed."

The illustrations of this invention, and we think it is a very clever idea, also do we not have any means of working out the practical. We believe that a patent can be obtained on this device; as far as is known to us, nothing like this exists.

Don't Let Constipation Burn You Up

No wonder you feel the heat, if you are constipated all the time. It's the condition of your body more than the temperature; the feverish results produced by the slow motion that is being induced into your system. No man or woman can be comfortable or healthy while this poison is getting in its deadly work. It shows in the way your bowels act. They are the barometer of your system. Why don't you throw away your worst enemy, and be rid of this terrible work? You know the trouble will be eliminated as soon as the bowel movements are taken care of. (Continued from page 243)

as
when the ions are not close enough together to mutually influence each other. The distance then that any ion travels before it hits another particle of the gas is called the mean free path. When an ion is acted upon, however, by an electric field the velocity with which it is either attracted to or repelled from an electrode depends directly on the strength of the field. In order to compare the velocities of ions we must compare them in equal fields so we use the term potential difference of gas to mean the energy of an ion is defined as the velocity of that ion in a field of unit potential gradient or a field of one volt full. The potential of the solvent potential gradient would exist between two electrodes charged to 10 volts if they were 10 centimeters apart.

The determination of the mobilities of ions is only possible in the determination of velocities. A convenient method of doing so was described in a previous paper, but it gives us a very convenient way of comparing ions in different gases and different kinds of ions to see how they behave in motion.

Early experiments showed that generally when travelling more rapidly than positive ions, i.e., had greater mobility and that both travelled somewhat along the same molecule so much so that in fact it was thought the ions must be larger, heavier bodies than molecules. Further experiments, carried out on 20 molecules in a chamber, and that the identities are always smaller. More recent work however has shown that in some gases negatives are not the same, whither at lower temperatures not travel as fast as would be expected, hence they may not be suitable for all, but the slowness of their motion may be rather due to the field. This is one of the most interesting points in Modern Physics, for it would show that the weight of an ion depended upon its charge of electricity, and recent discoveries support this view which will be discussed in the following paper. However it is important to note that recombination and diffusion tell us that the conductivity of a gas will be. It also gives us an idea of the size and charge of the ion.

RECLAIMING THE U-BOATS TOLL
BY NOVEL SALVAGE APPARATUS

(Continued from page 230)

points of resemblance and difference of these two groups of gaseous nebulae. They resemble each other in the nature of their light which gives the typical bright line spectrum of incandescent gases at low temperature and under low pressure. Their luminosity also may be due partly to reflected light, which the various gases are associated and partly to some form of electrical excitation as well as to light of incandescence. The gaseous elements that enter into the composition of both groups are hydrogen, helium and the unknown gas nebulae of helium, and neon. While the density of the gaseous nebulae is very small in proportion to the great volume of space they fill up the whole space is tremendously more extensive than the planetaries. Both show the presence of dark as well as luminous matter and show periodic phenomena, which we know of stars.

The two groups are all alike in showing a decided preference for the fundamental period of the star. In the densest star clouds.

As to their most marked points of difference the stars possess a very small, rather sharply defined disk-like appearance with a strong, star-like condensation at the center. They are also moving through space with a true space velocity.

SYMPHONY MFG. CO., DEPT. C, TOLEDO, OHIO

ANALYSIS OF IRREGULAR WAVE SHAPED ALTERNATING CURRENTS.

(Continued from page 247)

two simple sine waves, shown in light lines, as indicated. One of the sine curves has the same frequency as the resultant curve, while the other sine curve has three times this frequency.

The relative positions of the two component sine curves should be noted. Positive and negative lobes always start out from the zero starting point in the same direction, and always pass the horizontal datum line in the same way. The negative lobe of sine B could be turned about the horizontal datum line as an axis until it comes into the same plane with the positive lobe A, as indicated by the horizontal line and designated by C, the complete similarity and symmetry of A and C may be made apparent.

Fig. 4 shows the same two component sine curves, displaced somewhat in position, horizontally, and added together, and forming a resultant curve having a very different shape from that shown in Fig. 3. However, the symmetry of the positive and negative lobes A and C is to be noted.

Fig. 5 shows the same two component sine curves displaced still more in position, with a slightly different shaped resultant.

It is evident then that many different shaped curves may result from the algebraic addition of only two sine curves, by simple curve addition, in any manner changing their maxima values. Many different shapes

ty by mentioning the "Electrical Experimenter" when writing to advertisers.
would moreover reflect if the positions of the two sine curves were not changed while their maxima values were changed. Fig. 6 shows two sine curves changing in phase, with maximum value of only one of the component sine curves. The resultant curve in this case should be compared with Fig. 3. The harmonic frequency of the component curves is the same in both these figures.

Another important feature to be noted in comparing the resultant curves in Figs. 3, 4, 5 and 6 is that in passing from O to X one would arrive at the crest of the resultant curves, before arriving at the lower. The reason for this is that in Figs. 5 and 6, the feature of similarity or symmetry may be clearly established by imagining the lobes as occurring along the horizontal OX. This is precisely the case, as we have seen in the previous section of this article, and the resultant values are simply the amplitudes of the resultant sines, which are then taken in the place of the ordinates.

Curves resulting from the addition of sine curves whose frequencies are even multiples of the resultant curves are not symmetrical.

If then any alternating pressure or current curve obtained by experiment, is symmetrical as regards its positive and negative lobes, it is made up of sine-curve components whose frequencies are odd multiples of the fundamental frequency. Nearly all pressure and current waves found in practise, produced by electromagnet induction, are symmetrical in curves, and the statement is sometimes made that such curves or waves consist of the fundamental and its odd harmonics.

One practical method of determining a number of the harmonic curves or components sine waves comprising any given resultant wave curve, is by use of a frequency meter or a form of frequency meter, the vibrating reed form, is illustrated by Fig. 7. This instrument a number of small elastic or springy metallic strips or rods, 1, 2, 3, 4, etc., are carefully calibrated by filing or scraping them all rigidly fastened to the same metal base, B, having attached to it a thin iron tongue, T, which extends over the poles of an electromagnet, M. If a vibrating current is allowed to pass across the electromagnet, the iron tongue and metal base will vibrate with the same frequency as that of the alternating current. The particular reed that has the same natural frequency as that of the alternating current, will vibrate with considerable amplitude; thus indicating, if the reeds are all marked, the frequency of the wave. Fig. 7a shows the manner in which the frequency meter is worked. The table which follows gives the harmonics up to the 15th for higher frequency components only; for lower frequency components the reader may construct a table himself, similar to that here given, excepting that each successive harmonic has a lower frequency, but a higher wave length. Thus the 4th lower harmonic has a frequency of $\frac{4}{6}$ and a wave length of 4A. A table interested in this important subject should read the first article, which appeared in the "Electrical Experimenter", when writing to advertisers.
How I Improved My Memory In One Evening
The Amazing Experience of Victor Jones

"Of course I place you! Mr. Ad
don Sins of Seattle.

"If I remember correctly—and I

Mr. Bur

the lumbarman, introduced me to you at the luncheon of the

Seattle Rotary Club three years ago in May. This is a pleasure indeed!

I haven't laid eyes on you since that day. How is the grain business?

And how did that amalgamation work out?"

The assurance of this speaker—in the
crowded corridor of the Hotel

McAlpin—compelled me to turn and

look at him, though I must say it is

not my usual habit to "listen in"
even in a hotel lobby.

"He is David M. Roth, the most

famous memory expert in the United States," said my friend Kennedy, an

swering my question before I could get it out. "He will show you a lot

more wonderful things than that,

before the evening is over."

And he did.

As we went into the banquet room the

toastmaster was introducing a long line of the
guests to Mr. Roth. I got in line and

when it came my turn, Mr. Roth asked,

"What are your initials, Mr. Jones, and

your business connection and telephone number?" Why he asked this, I learned later, when

he picked out from the crowd the

60 men he had met two hours before

called each by name without a mis-

take. What is more, he named each man's

business and telephone number, for good measure.

I won't tell you all the other amazing

things this man did except to tell how he talked back, without a minute's hesi-

tation, long lists of numbers, bank clear-

ings, prices, lot numbers, parcel post rates and anything else the guests gave him in

rapid order.

**********

When I met Mr. Roth again—which you

may be sure I did the first chance I got—he rather bowed me over by saying, in his

quiet, modest way:

"There is nothing miraculous about my

remembering anything I want to remem-

ber, whether it be names, faces, figures,

facts or something I have read in a mag-

azine.

"You can do this just as easily as I do.

Anyone with an average mind can learn to

do it quickly and easily the same things

which seem so miraculous when I do them.

"My own memory," continued Mr. Roth,

"is not very faulty. Yes it was—

a really poor memory. On meeting a

man I would lose his name in thirty sec-

onds while now there are probably 10,000

men and women in the United States, many

of whom I have met but once, whose names I can call up like magic.

"That is all right for you, Mr. Roth," I

interrupted, "you have given years to

it. But how about me?"

"Mr. Jones," he replied, "I can teach

you the secret of a good memory in one-
evening. This is not a guess, because I

have done it with thousands of pupils. In

the first of seven simple lessons which I have prepared for home study, I show you

the basic principle of my whole system and you will soon know if you have

as good a memory as you may fear—but just like playing a fasci-

nating game. I will prove it to you."

He didn't have to prove it. His Course
did: I gave it a trial and I was satisfied. Since

he said his publishers, the Independent Corporation.

When I tackled the first lesson, I sup-

posed I was the most surprised in forty-
eight states to find that I had learned—in

about one hour—how to remember a list of

one hundred words so that I could call them

out forward and back without a single mis-

take.

That first lesson stuck. And so did the

other lessons.

Read this letter from C. Louis Allen, who

at 32 years is president of a million dollar

corporation, the Pyrene Manufacturing

Company of New York, makers of the fa-

mous fire extinguisher:

"Now that the Roth Memory Course is

finished, I want to tell you how much I

have enjoyed the study of this most fas-

cinating subject. Usually these courses in-

volve a great deal of drudgery, but this has

been nothing but pure pleasure all the way

through. I have derived much benefit from

taking the course of instructions and feel

that I shall continue to strengthen my mem-

ory. That is the best part of it. I shall be

glad of an opportunity to recommend your

work to my friends."

Mr. Allen didn't put it a bit too strong.

The Roth Course is priceless! I can

absolutely insist on my memory now, can
call the name of most any man I have

met before—and I am getting better all the
time. I can remember any figures I wish to

remember. Telephone numbers come to mind instantly, once I have filled

them by Mr. Roth's method. Street addresses are just as easy.

The old fear of forgetting (you know

what that is) has vanished. I used to be

"scared stiff" on my feet when I got on my

feet at the club, or at a banquet, or in a

business meeting, or in any social gath-

ering.

Perhaps the most enjoyable part of it all

is that I have become a good conversation-

alist—and I used to be as silent as a

sphynx when I got into a crowd of people

who knew things.

Now I can call up like a flash of light-

ning most any fact I want right at the in-

stant. I find it hard to believe that a "hair trigger" memory belonged only to the

proselyt and genius. Now I see that every

man of us has that kind of a memory if he

only knows how to make it work right.

I tell you it is a wonderful thing, after

growing up in industry, that it has taken

so many years to be able to switch the big search-

light on your mind and see instantly

everything you want to remember.

This Roth Course will do wonders in

your office.

Since we took it up you never hear any-

one in our office say "I guess" or I

think it was about so much" or I "forgot

that right now" or "I can't remember" or

"I must look up his name." Now they are

right there with the answer—like a shot.

Have you ever heard of "Multigraph"

Smith? Real name H. Q. Smith, Division

Manager of the Multigraph Sales Company, Ltd., in Montreal. Here is just a bit from

a letter of his that I saw last week:

"Here is the whole thing in a nutshell:

Mr. Roth has a most remarkable Memory Course. It is simple, and easy as falling off a

log. Yet with one hour a day of prac-

tice, anyone—I don't care who he is—can

improve his Memory 100% in a week and

1,000% in six months."

My advice to you is don't wait another

minute. Send to Independent Corporation

for Mr. Roth's amazing course and see what

a wonderful memory you have got. Your

dividends in increased earning power will

be enormous.

VICTOR JONES

Send No Money

So confident is the Independent Corpora-
tion, the publishers of the Roth Memory

Course, that once you have an opportunity
to see in your own home how easy it is to
double, yes, triple your memory power in a

few short hours, that they are willing to send

the course on free examination.

Don't send any money. Merely mail the

coupon or write a letter and the complete

course will be sent, all charges prepaid, at

once. If you are not satisfied with it, return it

back any time within five days after you

receive it and you will owe nothing.

HOW THREE NEW YORK SUBWAYS MEET AND PASS

(Continued from page 226)

Along 42nd street between "Times Square" and the "Grand Central" terminal, will undoubtedly take place the heavy cross-traffic between the two systems.

Reverting once more to the old subway system, which extends northward in the lower part of the "42nd Street" line, this will be operated as previously and will be extended by the Interboro Rapid Transit Company so as to proceed from the "Grand Central" terminal northward along Lexington Avenue, cross under the Harlem River at 120th Street and from this point it will branch out underground along Mott Avenue, via subway to 157th Street, from which point it will operate as an elevated line along Jerome Avenue to Woodlawn. After crossing under the Harlem River, this subway route will have a second branch extending eastward to 147th Street and Southern Boulevard. There before it will run via subway along Southern Boulevard and eventually change to an elevated line at Bancroft street. From here it will operate as a local route from 157th Street to the Eastern Boulevard. The new Interboro subway plans call for the extension to the present "Bronx Park" division, via elevated road, northward to 241st Street.

THE DESIGN AND USE OF THE AUTOMATIC REPEATING RIFLE

(Continued from page 249)

the current thru the buzzer coils, charges up the condenser C of the wave-meter, which in turn discharges thru the inductance L, producing radio frequency oscillations in the circuit CL. These in turn are broken up into a group frequency depending on the pitch of the buzzer. Another oscillating circuit brought into induction with the wave-meter will pick up energy as explained in several places throout this article.

VII. Measurement of Mutual Inductance

Figure 8 shows the method used in measuring the mutual inductance between two coils such as two coils of a varimeter or loose coupler. A known capacity C, is connected in shunt with the two inductances L1 and L2 which are connected in series with each other. A double-pole, double-throw switch is connected in circuit as shown so as to reverse the current in coil L2. When the switch is thrown to the side A, current flows thru the two inductances in the same direction, thus causing a current to be set up in the same direction or sid. In this position the two coils are said to be aiding.

When the switch is thrown to side B, current passes thru the coils in opposite directions, causing their fluxes to oppose each other. In this position the coils are said to be opposing. If now a wave-meter is brought near the coils the wave-length of the current can be measured on each position of the switch. Then knowing the value of the capacity and the wave-length it corresponds to in each position of the switch, the value L1 and L can be computed.

\[ L = L_1 + L_2 + 2M \]
\[ L = L_1 + L_2 \]
\[ M = L_1 - L_2 \]

where \( M \) = mutual inductance between \( L_1 \) and \( L_2 \)

L = inductance with the two coils aiding

L = inductance with coils opposing

L1 and L2 = inductance of two coils

All values in cms.

Now measuring the mutual inductance for various positions of the coils with respect to one another, as for instance, the angle of displacement between the two coils of the varimeter or the distance one coil is inside another, we should be able to use the above coupler, we can plot a curve of mutual inductance against coil position.

VIII. Measurement of the Coefficient of Coupling

The measurement of coupling is a very important measurement in radio engineering, for upon it depends the sharpness of sympathy of transmitters and receivers. Coupling is usually determined by all over 20% being considered tight coupling and all below 20% being considered loose coupling.

In order to measure coupling, the following procedure is followed: The circuit is connected as in Fig. 8, and the mutual inductance (M) measured. Then the self-inductance of the two coils as explained under III, and from this data the coupling is found by substituting in the formula:

\[ K = \frac{M}{\sqrt{L_1 L_2}} \]

where \( K \) = per cent coupling

M = mutual inductance in cms.

L1 and L2 = inductance of two coils in cms.

A curve can be plotted in this case also, showing the per cent coupling against the position of the coils.

IX. Measurement of the Distributed Capacity and Natural Period of Inductance Coils

Any coil has a certain amount of distributed capacity between each section of this coil combined with its self-inductance causes the coil to respond to some wave-length which is known as its natural period. A receiving set having a coil therein that has a natural period within the range of the receiver is very inefficient, because at some wave-length the coil cannot operate at its own natural period, and weaken the received signals considerably by absorbing energy in order to keep itself in a state of oscillation. The solution is to use a lessener degree with the transmitting helix, and for this reason helices usually have only enough turns to give the required capacity, while receiver inductances are split up, in fact by means of end-turn switches or "dead-end" breaks.

The accompanying figure 9, delineates the method of measuring the natural period of a coil. The wave-meter is excited by a buzzer and inductively coupled to the coil being measured; the measurement is taken across the terminals and is limited to the connection of the telephone and detector. As the condenser of the wave-meter is moved across the handle a fixed point will be found that gives a loud signal in the telephones. This is the natural period of the coil.

By extending the self-inductance and natural period of a coil the distributed capacity is calculated from the wave-length formula. The method of measuring the total distributed capacity is not strictly accurate, but is good enough for most practical purposes.

Conclusions

This concludes our series of articles on the wave-meter, and the author hopes he has duly impress upon the reader the wide range and variety of uses to which a wave-meter can be put. In fact it can be easily seen that a wave-meter is a wider necessity in a radio laboratory and with this one simple meter practically every important measurement used in Radio Engineering can be made.

(Conclusions)
No. EX3002

"THE BOY'S ELECTRIC TOYS" contains enough material to make and complete over twenty-five different electrical apparatus without any other tools except a screw-driver furnished with the outfit. The box contains the following complete instruments and apparatus which are already assembled:

Student's chromic plunge battery, compass-visual meter, solenoid, telephone receive and electric lamp. Enough various parts, wire, etc., are furnished to make the following apparatus:

Electromagnet, electric compass, magnetic pictures, dancing spiral, electro hammer, galvanometer, voltmeter, book for telephone receiver, condenser, sensitive microphone, short distance wireless telephone, test storage battery, shock coil, complete telegraph set, electric riveting machine, electric buzzer, dancing fishes, singing telephones, mysterious man, electric jumping jack, magnetic geometric figures, rheostat, erratic pendulum, electric butterfly, thermo electric motor, visual telegraph, etc.

This does not by any means exhaust the list, but a great many more apparatus are built actually and effectually.

With the instruction book which we furnish, one hundred experiments can be made with this outfit listed, nearly all of these being illustrated with superb illustrations. No other materials, goods or supplies are necessary to perform any of the one hundred experiments or to make any of the 25 apparatus. Everything can be constructed and accomplished by means of this outfit, two hands, and a screw-driver.

The outfit contains 114 separate pieces of material and 24 pieces of finished apparatus ready to be used at once.

Among the finished material the following parts are included: Chromic salts for battery, lamp socket, bottle of mercury, core wire (two different lengths), a bottle of iron filings, three spoons of wire, carbons, a quantity of brass screws, flexible cord, two wood bases, glass plate, paraffine paper, binding posts, screw-driver, etc., etc. The instruction book is so clear that anyone can make the apparatus without trouble, and besides a section of the instruction book is taken up with fundamentals of electricity to acquaint the layman with all important facts in electricity in a simple manner.

We guarantee satisfaction.

The size of all of the outfit is 14 x 9 x 2 1/2. Shipping weight, 3 lbs. $5.00

No. EX3002 "The Boy's Electric Toys" outfit as described.

Laboratory Chemistry

Experimental Electricity Course
This masterpiece contains 160 pages, 400 illustrations. Size of book 5½"x9". Printed on extra thin paper, so book can be slipped into pocket. Handsome stiff cloth cover. FREE with a year's subscription. Add 5c for postage.

Wireless Course
The most comprehensive Wireless Course ever printed. Contains 160 pages, 350 illustrations. Size of book 6½"x9". Very fine flexible linen cover. FREE with a year's subscription. Add 5c for postage.

Read This Remarkable Offer

It may be withdrawn at any time, due to the tremendous cost of paper, which IS JUST DOUBLE WHAT IT WAS ONE YEAR AGO. We only have a limited supply of these fine books on hand; after they are gone we cannot reprint the books until conditions become normal again. THIS MAY BE TWO YEARS OR MORE. Now is your chance. The publishers of this journal have earned an enviable reputation of giving more than 100 cents' worth for each dollar spent with them. Profit by this liberal opportunity NOW; it may never be made again.

HERE'S THE OFFER

Subscribe to the ELECTRICAL EXPERIMENTER for one year, at the regular subscription price of $1.50 per year (Canada, foreign and N. Y. C. $2.00) and we will send you FREE any one of the above books. If you subscribe for two years, TWO BOOKS WILL BE GIVEN FREE. All THREE BOOKS will be sent FREE with a three-year subscription. If you are a subscriber at present, take advantage of this wonderful opportunity anyway. If you do, we will extend your present subscription from its expiration date.

This Offer Limited. Act Now.

Flexible Covers
Handy Pocket-Size Volumes

Just what you need to know to succeed in ELECTRICITY

EVERY electrician, every engineer, every mechanic should know about these wonderfully helpful instructive books, which give in plain words a complete working knowledge of electrical engineering in all its phases.

You run into some new electrical problem almost every day. The information you need to help you in your every day work is in

HAWKINS ELECTRICAL GUIDES

These books place electricity at your finger ends. They cover every imaginable subject, principle, theory, problem, trouble, and way of doing things electrically. Every subject is indexed so that you can turn right to it. They are a study course and a reference guide in one, written in plain everyday language, in readable words—only what you need to know—check full of up-to-the-minute electrical knowledge.

The guides are a complete course in electrical engineering. They will help you in every phase of the day's electrical work. You can't ask an electrical question that Hawkins Guides can't answer.

Pocket-Size Flexible Covers

The books are small enough to slip into your coat pocket—handsomely bound in flexible braided covers.

You can carry each volume with you until you have worked through the entire course of 3,750 pages of actual information and 4,700 illustrations. A pair of these books and you'll have knowledge enough to go almost anywhere.

SEND NO MONEY

It will cost you nothing to receive these books—to look at them over—and see all the questions you can think of—use them, work with them—pick up some information that will increase your earning ability. We will ship you the entire set of 10 volumes entirely FREE.

You need not buy any books. Any one or more of these books can be returned to us at any time. You will be under no obligation. You need not pay one cent for any of these books.

72 Fifth Ave.
New York, N. Y.

Amazing Opportunities in the AIRPLANE INDUSTRY

Never before have ambitious men had such a glorious chance as is offered today in this wonderful industry. The war news only proves that the Airplane has come to stay—that thousands and hundreds of thousands of airplanes will be demanded for commercial uses when peace returns.

Meanwhile an army of trained men must be found to man the new aeroplane factories that are being built everywhere. This makes the big chance for you—a chance of a lifetime. Enroll NOW for our complete Course of training in Practical Aeronautics and the Science of Aviation, and prepare yourself in a few short months to double or treble your present salary.

We Teach You by Mail
In Your Spare Time at Home

Our new, scientific Course has the endorsement of airplane manufacturers, aeronautical experts, aviators and leading aero clubs. Every Lesson, Lecture, Blue Print and Bulletin is self-explanatory. You can't fail to learn. No book study. No schooling required. Lessons are written in non-technical, easy-to-understand language. You'll not have the slightest difficulty in mastering them. The Course is absolutely authoritative and right down to the minute in every respect. Covers the entire field of Practical Aeronautics and Science of Aviation in a thorough, practical manner. Under our expert direction, you get just the kind of practical training you must have in order to succeed in this wonderful industry.

Special Offer NOW
SEND THIS COUPON TODAY

It is our duty to help in every possible way to supply the urgent need for graduates of this great school. We have facilities for teaching a few more students and to secure them quickly we are making a remarkable Special Offer which will be withdrawn without notice. Write today—or send the coupon—for full particulars. Don't risk delay. Do it now.

Prepare for one of these positions

Aeronautical Instructor
$60 to $150 per week.
Aeronautical Engineer
$100 to $300 per week.
Aeronautical Contractor
Enormous profits.
Aeroplane Repairman
$60 to $75 per week.
Aeroplane Mechanician
$40 to $60 per week.
Aeroplane Inspector
$50 to $75 per week.
Aeroplane Salesman
$5,000 per year and up.
Aeroplane Assembler
$40 to $65 per week.
Aeroplane Builder
$75 to $200 per week.

LARGEST CIRCULATION OF ANY ELECTRICAL PUBLICATION
FREE BE A CERTIFICATED ELECTRICIAN

YOUNG MEN LISTEN

The country needs more trained, graduate electricians. Thousands have gone into the Government service and there is such an unusual demand for competent electrical men that I am making a wonderful offer at this time. HERE IS YOUR OPPORTUNITY! I want to send you my splendid offer now.

Don't hesitate because of age or experience. Young men, boys and old men must now fill the gaps and keep business going. DO YOUR PART. Prepare yourself for a real position by my Home Study Course in Practical Electricity. I am Chief Engineer of the Chicago Engineering Works. I have trained thousands of men and can help you better than anybody else. We also have large, splendidly-equipped shops where you can come at any time for special instruction without charge. No other correspondence school can give you this.

SPECIAL OFFER: Right now I am giving a big, valuable surprise that I cannot explain here, to every student who answers this ad. Write today!

$46.00 to $100.00 a Week

Go after some real money. Qualify for one of the thousands of splendid positions open. All you need to start is a few months snappy, practical instruction from a competent engineer. Come to me—NOW. I'll give you my personal care to ensure rapid and efficient progress. My course is intensely practical. It is highly condensed, simplified, up-to-date and complete. I am so sure you will make a splendid success in this study, that I will Guarantee Under Bond to return to you every cent paid for tuition, if you are not entirely satisfied when you receive your Electrician's Certificate granted you as a graduate of my school.

FREE—Lessons and Outfit—FREE

Send me the Free Outfit Coupon at once. Do it now! For a limited period I am making a slashing cut in the cost of tuition, and giving each new student a grand outfit of Electrical Tools, Material and Instruments—in addition—Absolutely Free. I will also send you—free and fully prepaid—Proof Lessons to show you how easily you can be trained at home to enter this great profession, by means of my new, revised and original system of mail instruction.

ACT PROMPTLY

Get the full benefit of this great offer. Send the Coupon or a postal for free information without delay. Do it now—before my free offers and guarantee are withdrawn.

ELECTRICITY

AS EXPERTS KNOW IT

Learn electricity as you would in actual PRACTICE—in accordance with the methods employed by the highest paid electrical experts in America. The New McGraw-Hill Library of Practical Electricity contains the actual working facts which you need in order to succeed in the electrical field. Terrell Croft, formerly with the Westinghouse Company, makes the conquest easy for you.

A New Standard in Electrical Literature

The New Library of Practical Electricity by Terrell Croft marks a new era in electrical literature.

The great field of electrical engineering, with its limitless possibilities of earning power, is brought to you in a form that makes success easy. The Library is a creation—an achievement that is without parallel in technical literature, because it sticks to actual practice throughout its 5000 pages.

$2 per month starts you to bigger pay

(CROFT'S NEW LIBRARY OF PRACTICAL ELECTRICITY—8 VOLS.)

Now is the time to master Electricity—Now is the time to prepare for a high salary

Old books won't do. Amateurish books won't do. Books compiled by "desk authors" or men with no practical experience will not serve your purpose.

Practical books are easiest mastered. Practical books, written by practical men, teach you accurately and rapidly. There is nothing in the Croft Library which you cannot understand. Terrell Croft tells you the secrets of success in electricity in plain words, figures and illustrations. Nothing is left to the imagination. There is no guesswork. There is no theory or higher mathematics.

Send for these eight volumes. No matter how many books on electricity you possess, you are unfair to yourself unless you take advantage of this free examination privilege. No matter whether you are beginner or expert, these books will show you the clear road to success. Inspect them now.

McGraw-Hill Book Co., Inc.
239 West 39th Street, New York, N.Y.

"See them First—Pay afterwards"

A letter that means something to YOU—

McGraw-Hill Book Company, Inc.,
239 West 39th Street,
New York, N.Y.

Gentlemen: In an attempt to express myself about CROFT'S NEW LIBRARY OF PRACTICAL ELECTRICITY, I have never seen, and do not believe there was ever printed in the English language, a more comprehensive set of books. It is a library that is just as valuable to the novice as to the expert, because it is all practice.

Respectfully,
GUY H. PEIFER,
Chief, Duplan Silk Corporation,
Hazleton, Pa.

Now one cent in advance—Just the coupon

Examine this new Library for ten full days without expense. Find out for yourself why it is now taking the lead in electrical book sales in America. Use the books as you see fit for ten days. Look at the hundreds of illustrations that clear up all the mysteries in electrical practice. Slick a couple of the volumes in your pockets, and refer to them during the day. Figure out in an instant the problems that have hitherto defied solution.

Then send us $2 per month for eight months, or return the set entirely at our expense. You risk nothing by returning the attached coupon.

September, 1918
383 Electrical Experiments for Each Student
ONE SUPERIOR WAY BY WHICH THIS SCHOOL MAKES ELECTRICIANS AND ENGINEERS

THREE hundred and eighty-three experiments a year—for you to work out yourself! And the most modern electrical appliances, apparatus, machines, laboratory and work-shop materials with which to work, by which to learn from actual experience! Also, a series of practical lectures, and just the necessary text book instruction! All under the guidance of an able faculty composed of practical, electrical men chosen from high positions in the actual field of electrical practice. That is what you can get at this school, and that is what you need to succeed. And isn’t that ideal system of electrical education just what you want? Mail the coupon now for complete details about this school and all its advantages.

ELECTRICIAN DIPLOMA IN 1 YEAR.
Here you can obtain a recognized Electrician Diploma in one year—twelve months; and with the practical method of thorough instruction, training and development here (as referred to above) you will graduate with that ability the electrical world demands and recognizes, and for which high salaries are paid. And your school life here will be so fascinating the 12 months will be the best and most profitable of your life. No matter what your past education you can enter the electrician class here. Mail the coupon now for details.

B. S. AND E. E. DEGREES IN 3 YEARS.
This school teaches Electrical Engineering also—and gives Bachelor of Science and Electrical Engineer’s Degrees of recognized standing under the laws of Wisconsin—in 3 years (36 months). This substantiates this school’s standing and ability and the higher, recognized electrical education you can obtain here in a short time.

Young men with High School diploma, or the equivalent are accepted in the Electrical Engineering Department. Others who finish the Electrician’s Course with diploma can enter Electrical Engineering class—and receive degrees referred to in 3 years. Mail the coupon and get complete information about Electrical Engineering here and Degrees given.

ONE SUBJECT—ALL ITS BRANCHES.
Electricity only in all its branches—free coupon lower left is taught here. Consequently the instruction, training and development you will receive here will be more thorough; you will learn more in a shorter time and at less expense by enrolling here. This is not a school of many different subjects; nor is it a little school. This is an institution of thorough practical education, training and development.

POSITIONS FOR GRADUATES.
This school enjoys the highest regard of electrical industries, and those employing master electricians and engineers because of the ability of its graduates, due to the practical and thorough instruction, training and development given here, in accordance with the electrical world’s requirements. And large concerns look to this school for their biggest electrical men. Consequently, this school can furnish splendid positions to its graduates. So that your success is certain if you enroll here—your success begins the moment you enroll. Soon as you graduate you can have a position and be accepted by the electrical world as an electrical man of ability—not a boy just out of school.

 YOU CAN EARN WHILE YOU LEARN.
In addition to the practical instruction, training and development given at this school, an arrangement exists with large companies whereby students of this school can have employment one-half day and attend classes, lectures and laboratory tests one-half day, receiving pay for their outside work which can go toward helping to pay living expenses, etc., here. And besides the money thus received students obtain actual business or technical experience which is of extreme value for their future. Prospectus outlines this “Earn While You Learn” plan—mail the coupon.

SCHOOL OF ENGINEERING OF MILWAUKEE

CLIP THIS COUPON AND MAIL NOW

ANY BOY OR YOUNG MAN CAN ENTER THIS SCHOOL, NO MATTER WHAT HIS EDUCATION

There is the proper starting place here for every young man whatever his past education or present ability. The main requirement for entrance in this school is the ambition to succeed, and the will to work. Whatever your age or education you can enroll here—and you’ll be advanced as your ability warrants. This is an educational course for all electrically ambitious young men—and will give you the unequalled advantages and benefits that the future electrical world will derive.

Next Term Starts

September 2

Prepare to Enroll on That Day

START here September 2—or sooner if you like—and start at once to get the superior, thorough, practical electrical education, training and development this school gives. Start now—and graduate the sooner, instead of waiting until later, and graduating later. Begin your life’s success at once. Special privileges granted to those subject to draft this year or later—explained in prospectus. Mail the coupon at the left. Get all the information NOW. Prepare to enroll September 2—Your Success Starting Day.
COLD FROM ELECTRICITY

If we pass an electrical current thru a metallic wire, the latter becomes heated. The thinner the wire and the larger the current, the greater the heat in the wire. All of our incandescent lamps work on this principle, as do our electric irons, toasters, water heaters, etc.

But few people know that electricity can and does produce cold direct, merely by passing from one certain metal to another. Nor is it a recent discovery. The device, termed "Peltier's Cross" after its French inventor, Peltier, was demonstrated in the middle of the last century. Briefly, the apparatus consists of two bars of metal, one being Antimony, the other Bismuth. The two bars are soldered together at right angles forming a cross. If we now pass a current thru the cross by connecting the positive pole of a battery to the Bismuth bar, and the negative pole to the Antimony bar, the point of junction between the two metals becomes rapidly cooled.

If we drill a shallow hole into the top bar and fill it with water, it soon turns into ice, proving the experiment.

This phenomenon is of course well-known to the electrical man, but the very surprising fact is that it has never been turned into practical use during all these years. Of course, it goes without saying that the original Peltier's Cross is not an efficient apparatus—it would be decidedly expensive in time as well as money to freeze ice cream this way!

But the principle is certainly there, and it is pretty well understood by the scientist; all it needs is improvement. And right here lies a wonderful gold mine for the man who turns out an economical electrical apparatus to produce cold commercially. Think of all the ice-less refrigerators, ice-less ice chests, ice-less ice cream freezers and what-not, for which we are eagerly waiting. It is the benefactor who will lift the great American curse—ice water! Ice water is responsible for more ruined American stomachs, and for more dyspepsia than all the other causes combined.

Water cheaply cooled to near the freezing point is what we need, so our doctors tell us. When will we see the first direct electrically cooled carafe, with its wire-covered net work, and a plug connecting it with the chandelier above the dining table?

And where is the still greater benefactor who will increase our working capacity one hundred per cent when the thermometer stands over 90°? During torrid spells, even in moderately hot weather, the entire world slows down. You simply can't work your best during the dog days, even if you happen to sit in a bathtub full of cold water, as I am doing just now, trying to write this Editorial! (The heat, by the way, furnished the idea for it.)

From late spring to early winter, millions of radiators stand idle all over the world. Why have we not sufficient intelligence to turn these perfectly good heating plants into cooling plants? The system is in the house and waiting, but we are too stupid to start the freezing water thru it, and thus reduce the room temperature to 70° or less. A visitor from Mars would laugh his head off while walking into our offices where the already hot air is made still hotter by fans—which do not cool the way, but increase the temperature. (Put your hand on a running fan—if it is not too hot—and you will know why fans do not cool a room.) Our visitor could not possibly understand why our radiators were hot instead of cold.

But we will not always be children. Some day we'll grow up and then we will know enough how to keep cool in summer, be it in the office, the house, or in the subway. But when that day comes, be prepared to shut all doors and windows, just as you do in the winter. If you don't your room will become hot just as it becomes cold in the winter, should you leave the door open again.

Yes, and then we'll all have summer colds, to be sure! 

H. Gernsback.
‘LEARN BY DOING’
The Only Way to Learn Electricity

The only way you can become an expert is by doing the very work under competent instructors, which you will be called upon to do later on. In other words, learn by doing. That is the method of the New York Electrical School.

Five minutes of actual practice properly directed is worth more to a man than years and years of book study. Indeed, Actual Practice is the only training of value, and graduates of New York Electrical School have proved themselves to be the only men that are fully qualified to satisfy EVERY demand of the Electrical Profession.

At this “Learn by Doing” School a man acquires the art of Electrical Drafting; the best business method and experience in Electrical Contracting, together with the skill to install, operate and maintain all systems for producing, transmitting and using electricity.

No previous knowledge of electricity, mechanics or mathematics is necessary to take this electrical course. You can begin the course now and by steady application prepare yourself in a short time. You will be taught by practical electrical experts with actual apparatus, under actual conditions. 5,000 of our students are today successful electricians. Come in and read their enthusiastic letters. Let us explain this course to you in person. If you can’t call, send now for 64-page book—it’s FREE to you.

SCHOOL OPEN ALL SUMMER.

How the Electric "Sea Tanks" Raided Pola

THE very latest war-time animal is the electric "Sea Tank" as used by the Italians in a recent naval raid on Pola, Austria's famous naval base. From the information available on this latest hybrid among war-time offensive devices, it is learned that the Sea Tanks measure about forty feet in length and six feet in width, and that they are propelled by electricity. Further, as our illustration herewith shows, these Sea Tanks are provided with an endless rotary chain, running lengthwise around the vessel, these rapidly moving chains being fitted with sharp steel barbs or knives which can cut their way thru nets and other obstacles just like their prototypes, the land tanks, first used so effectively by the British. This under-water demon is provided with several torpedo tubes at the bow, and from all accounts, it seems that the device was crewless, and operated by means of electrical control currents sent thru a flexible insulated cable their way thru the heavy steel nets spanning the navigable approaches to the port, within which there lay at anchor Austria's fighting fleet, and that a mighty Austrian battle-ship of the "Venusa Unitis" type of about twenty thousand tons displacement was torpedoed.

The account of the attack on Pola by the Italian Sea Tanks states that they bored the steel belts carrying the net-cutting knives or barbs are driven by powerful electric motors, which obtain current from a storage battery carried in the Italian Under-water Tank, also the arrangement whereby the steel belts carrying the net-cutting knives or barbs are driven by powerful electric motors, which obtain current from a storage battery carried in
How Artillery Observation Balloons 'Phone to Earth

When the artillery observers of our army in France, go up in balloons for the purpose of spotting the shell hits and correcting the ranges, they must have a very safe and sure means of communicating with the artillery officer on the ground.

The photograph here shows a telephone dug-out in France with two United States soldiers, who are in direct telephonic communication with the aerial observer on board a balloon above virtue of a thin copper wire which runs up to the balloon. As a work of the aerial balloon observer is more or less hazardous, and it not infrequently happens that the observer's balloon is shot down by an enemy shell, in which case he must use his wits and endeavor to make a safe landing with his parachute. On the other hand, it has often been remarked by officers who have had the opportunity of seeing service near the European battle-fronts, that these observation balloons sometimes remain aloft and unsought for days at a time. The work is extremely interesting and plenty of volunteers are always available. It takes a man of keen sight and quick perception to fulfil the duties of an observation officer, as the changes in range in some cases have to be made very quickly in order to bring about a certain military maneuver. We may safely entrust this task to Pershing's boys.

The electrical control cable in such devices as this, and where it is of any considerable length, is invariably coiled and stored in the tank or torpedo, as otherwise the device would be extremely powerful in order to pull the constantly increasing length of cable thru the water if it were swung out like a grappling hook on the tender ship.

It is entirely feasible for a device of this kind to be controlled by a warship of the destroyer class at a distance of seven miles or even eight to ten miles or more. With ingenuity and the proper design of the device the type here under discussion, and in consideration of the undoubtedly proven cleverness of the Italian engineers, there is no doubt but what such a device could be sent out and steered so as to be encountered when it neared the steel nets and to bore its way thru them, and then to rise again; also at this juncture the observation officer on the war vessel looking thru his night glasses, could press the proper electric control button and cause one or more torpedoes to be discharged at an enemy war vessel in the manner described in the report from Rome, and which now forms a part of Italian naval history.

In any event, the Sea Tank would appear to be an invaluable antagonist against such war measures as harbor nets and the like, and it is conceivable that when desired to carry a crew, and providing the craft with a powerful under-water searchlights, such a machine should prove highly effective in clearing out mine fields, and breaking up swarms of mine-infested waters as those leading up to the great German naval base at Heligoland. This maneuver by the Italian Sea Tanks in their attack on Pola may seem all the more practical and possible to the layman when it is considered that the entire Gulf of Venice is very shallow—about 120 feet at greatest depth— and such an underwater fighting monster might crawl even along the bed of the Gulf of Venice and tackle the steel nets and mines protecting Pola, much in the same manner as a gigantic turtle would crawl along the bed of a lake. In fact, some engineers venture the opinion that with the proper design of the moving caterpillar belts and bars, that the Tank could be made self-propelling in the same manner as just mentioned.

It is most probable however, that the Italian Sea Tank as now used is fitted with powerful propellers the same as the submarine, and also that it has a suitable rudder for the purpose of steering it. To prevent the cable from becoming fouled in the propeller blades, the latter are encased in substantial steel cages. The pilot light or lights are provided with shields at the front, so as to throw intermittent signal flashes sternward, and by arranging this on a telescopic mast the officer in charge can, by simply pressing the proper button, cause them to rise ten to fifteen feet above the back of the Sea Tank while it is progressing thru the water near its objective. When the Tank has prostrated sufficiently near the net or other obstruction it is to burrow thru, the proper electrical impulses are sent over the electrical control cable which starts up the water-ballast tank motor, and by filling the tanks, the craft is caused to submerge. It is a simple matter and one which has been used herefore to provide a suitable electrical position indicating arrangement, whereby it becomes possible to know at any instant the direction and location of the "Sea Tank" while it is submerged. By means of a sensitive microphone installed in the vessel, it would be possible to ascertain when the Tank had chewed its way thru the enemy nets, and it could then be caused to approach the surface again if so desired. It is not believed however, that the vessel be made to come to the surface so as to show the signal light, for by means of the position indicator apparatus just described, its exact position at any time could be known and torpedoes discharged from it at an enemy war vessel swinging at anchor within the netted area.

An electrically equipped tremelo attachment for stringed instruments has been invented which produces the desired effects when buttons are pressed.

"Sea Tank" while it is submerged. By means of a sensitive microphone installed in the vessel, it would be possible to ascertain when the Tank had chewed its way thru the enemy nets, and it could then be caused to approach the surface again if so desired. It is not believed however, that the vessel be made to come to the surface so as to show the signal light, for by means of the position indicator apparatus just described, its exact position at any time could be known and torpedoes discharged from it at an enemy war vessel swinging at anchor within the netted area.

U. S. PATENT OFFICE NEEDS EXAMINERS

The U. S. Patent Office announces a need for technically trained persons for the examining corps of the Patent Office. Men or women are desired for practical education, particularly in higher mathematics, chemistry, physics, and French or German, and who are not subject to the draft for military service, to gain practical bench experience in addition to the above is valued. The entrance salary is $1,500.

Examinations for the position of assistant examiner are held frequently before the Civil Service Commission at many points in the United States. One is announced for August 21 and 22, in Chicago. For examination, places of holding the same, etc., may be had upon application to the Civil Service Commission, Washington, D. C., or to this office.

Should the necessity therefor arise temporary appointments of qualified persons may be made pending the holding of the regular Patent Office examination. Application for such appointment should be made to the Commissioner of Patents, Washington, D. C.
Balloon Microphones to Warn of Air Raids

By LEE A. COLLINS

In the scheme of aerial raid warning here proposed balloons are sent up and held secure by means of a strong rope or cable. Sensitive electric microphones are fastened to the under-harness of the balloon. All of the sound detectors are in series with a telephone receiver and a source of electric current by means of two wires which lead down by the cable.

Military Committee reports as one of the greatest scientific achievements of the war, the telephone arrangement whereby the position of enemy guns is determined. A portion of General Bell's statement follows:

All armies now employ scientific methods of locating guns which have never been employed in warfare before. One is known as the sound-ranging method. Briefly, they have observers scattered along a curved line, which has been accurately measured, and all of these observers, of whom there are usually six, utilize electric sound-ranging apparatus by which they report instantaneously the moment they hear the sound of a gun explosion. At a central point another electric apparatus records these sounds from the six different stations, and by a scientific method they combine the knowledge gained from these six points and succeed in locating with a remarkable degree of accuracy the position of the gun that made the explosion when it was fired.

Each side has a type of telephone which is able to hear distinctly over very considerable distances conversations not intended for the listener, and for a long time the Allies employed this system of gaining information without the knowledge of the enemy; but the Germans captured one of these instruments and discovered that their conversation in the trenches had been listened to for quite a while and that the president and general manager of the company, has just closed a contract for the installation. The power of the new station, it is announced, will be 11,000 kilowatts, and three towers will be erected, each the size of Eiffel Tower.

IMPROVE NAUEN WIRELESS PLANT.

The German wireless station at Nauen has been greatly improved since the outbreak of the war, according to the Frankfurter Zeitung. Instead of a single transmission tower 300 feet high, it now has ten towers ranging in height from 890 feet to 300 feet, while the distance thru which messages can be transmitted has been extended to 6,200 miles. The Frankfurter paper is quoted as saying that the Nauen services have proved invaluable for instructing cruisers and U-boats and that both the Goeben and Breslau received thru Nauen instructions to steam into the Bosphorus.

A Number of French Cities Are Equipt With a Specially Sensitive Microphone "Listening-Posts" Placed On High Buildings or Other Elevated Structures, for the Purpose of Detecting the Approach of Enemy Aircraft. An American Inventor Here Proposes a Very Simple and Feasible Plan for Giving Aerial Alarm Protection to Our Towns and Cities. The Scheme Is Simple, Involves Two Balloons Which Carry a Series of Horns Pointing in Various Directions, Each Horn Being Connected With a Super-Sensitive Microphone; Each Microphone Is Connected By Its Wire to Earth, Where a Selective Switch and a Pair of Listening 'Phones Enable the Operator to Quickly Ascertain Which Microphone Is Being Actuated, and Thus Also From Exactly What Direction the Enemy Aeroplane Squadron Is Approaching. These Microphones Will Indicate the Approach of Aircraft Several Miles Away.

Balloons can be sent up all along our coasts or cities at suitable distances apart. In case an enemy aeroplane attempts to bomb our cities, the sounds of his aeroplane engine are caught by the sensitive microphone detectors and are heard thru the telephone receivers. One central listener could keep the receivers fastened to his ears and receive the alarm from all of the detectors, or a listener could be kept for each district that the balloons were guarding. A galvanometer indicator can be used instead of the receivers to give a signal of approaching enemy aeroplanes. The range of detection will probably be greater than most people estimate, as tests made with microphones in locating pieces of artillery have proved.

SOUND-RANGE TELEPHONES TO LOCATE GUNS.

Upon his return recently from the battle front in France, Major-General J. Franklin Bell in supplying information to the Senate
American Aviator Escapes Under Hun Electrified Fence

H

OW would you like to be captured by the Teutons, and after escaping from your captors, not to mention sleeping in swamps and woods by day, and subsisting on fruits and raw vegetables, finally reach the border line which meant your liberty, only to find that a deadly electrified wire fence stared you square in the face? Such was the experience of an American flier, Lieutenant Patrick O'Brien, member of the Royal Flying Corps of England, who managed not only to escape from his German captors, after having landed on Teutonic soil with his flying machine, but succeeded eventually in getting past the highly charged electric fence which guards every foot of the border land between Belgium and Holland. This fence serves three purposes. First, it prevents the Belgians from escaping into Holland; secondly, it keeps enemies from making their way to freedom; and thirdly, it prevents desertions on the part of German soldiers themselves.

The accompanying illustration shows one of the most remarkable experiences ever enacted by a war-tortured human being. When Lieutenant O'Brien finally emerged from his last hiding spot in the woods near the Holland border, he nearly ran into this electrified barbed wire barrier before he knew it, although he had previous knowledge of it.

The hero of our story first thought of trying to make a grand pale vault over the whole three fences including the central electrically charged one, but this idea was finally dropped as the triple fence covered a span of at least twelve feet, and in order to safely clear the last barbed wire barrier he would have had to vault at least ten feet high and fourteen feet across. With the possibility that the pole ever slpt he might be thrown on the charged wire and immediately electrocuted when in falling his body would establish the circuit between fence and ground.

Another idea which he unsuccessfully tried out was a ladder which could be placed against one of the fence posts, and this he built from small twigs and boughs which he found in the woods near the fence and bound them together with flexible twigs and strips from his underclothes.

Eventually Lieutenant O'Brien hit upon the idea which finally saved his life and gave him his liberty, and his plan is shown in the accompanying illustration. This was nothing else than to barrow under the electrified wire fence. However, this was not as easy as it may seem at first thought. The electrified fence measured about ten feet high and the charged wires were spaced about ten inches apart while the lowest charged strand was but two inches from the ground. This is not all, for when our brave Lieutenant had dug a considerable quantity of the soil away with nothing but his bare hands, he discovered a heavy underground wire about six inches below the surface of the ground. He had great difficulty in digging the earth away without being discovered by the sentry who walked up and down periodically along the German side of the fence, and again, the underground wire, which was as thick as a man's finger, would not give.

But Yankee pluck and courage finally won, and by tugging at this wire, which did not carry any charge but served merely as a guard wire against just such an escape as this, he caused the underground wire to give at several points along the fence. He then proceeded with extreme caution to crawl feet first and on his stomach thru the trench which he had dug with his hands. His nerves were none too good, but he knew that one false move of even one inch, would mean certain death, and in a few moments he successfully made the passage under the heavily charged wires and emerged into the final space between the central electrified fence and the final barbed wire which was the only remaining barrier between himself and his liberty. He kneeled down and offered thanks to his Maker for his miraculous escape, and a few minutes later he past safely between the strands of the final barbed wire into Holland.

GENIUS AND ULTRA VIOLET RAYS.

By J. MACHETTI

In a back number of the E. E. there appeared an article entitled "The Effect of Ultra Violet Rays on Milk and Other Aspects" by Dr. H. Imbination. In this he says that "the cerebral substance is decomposed by ultra violet rays causing sun-stroke, when the rays of the sun are sufficiently powerful to react on the body." He shows that it is not the heat that causes this, for we never hear of heat prostration "among workers in factories, pottery factories, etc., where a high temperature prevails. Yet these same men may be taken with a rays-stroke upon exposure to the sun."

Still it is a matter of some mystery to read in the memoirs and confessions of deceased geniuses that they accomplished better work in the intense sunlight. In fact some of them could not work unless the rays fell on their bare heads.

No doubt, the question has often presented itself to many, why many men of genius have preferred or had to compose in the scorching rays of the sun. But may we not find an answer in Dr. Bizzoni’s discovery. And when we see that genius and men of brains in the same pot, according to C. Lombroso, and that post-mortem examinations have shown degenerations of cerebral matter of these men, the mystery becomes more convincing. As the sunlight is rich in violet rays and they are capable of decomposing the cerebral substance, consequently they acted for such men digastral plants. We all know that many famous men have resorted to narcotics and other stimulants in aiding them in their creative works. So for these individuals the ultra violet rays acted as creative aids by effecting chemical changes akin to narcotic stimulants.

Also, light vibrations act beneficially by its penetration. But in the case of these men the dissolving power of the ultra violet rays was of greater consequence.

Among such "Philomiens" we find Rousseau, Lesage, Giordani, etc. Rousseau said that the action of the sun in the dog-days aided him to compose and he allowed the rays of the mid-day sun to fall on his head. The striking fact is that Rousseau’s brain showed, after death, a marked degeneration of one of the lobes. Lesage, in his old age, became animated as the sun advanced to the meridian, gradually gaining (Continued on page 351)
Making Synthetic Gems in the Electric Furnace

By GEORGE HOLMES, Ass. A.I.E.E.

THE history of jewels and the thrilling part they have played in the world's history would make the "Grimm's Fairy Tales" fade away into oblivion. Kings, Queens, Sultans and entire Kingdoms have been wrecked through the many intrigues and mysteries that have been connected with famous jewels of ancient times. There was Caesar, Anthony and Nero and the havoc they wrought on Rome and the splendid cities of the far famed east; not to mention Cleopatra, the charming Queen of the Nile, who put the skins under a number of happy rulers just because she was the best dressed woman in Egypt and changed her jewels seven times a day.

For centuries it was necessary to mine these wonderful gems, by the sweat of the brow; but now all this is changed for to-day in the very heart of New York City, a new expert electro-chemist in the person of Dr. Maurice Aisen is making precious stones with the aid of the electrical furnace that bid fair to rival all those of ancient times.

There are more large and beautiful diamonds in the world today than rubies and this has a curious explanation. Ages ago was not until the fifteenth century that the present rotating wheel method of polishing them was introduced.

In the olden days the manufacture of a perfect stone was a long and tedious operation. To-day it is a fact that jewels can be analyzed, the component minerals found, then the same proportion of ingredients assembled and synthetic jewels actually manufactured, which equal Nature's own product.

Some of the earliest experiments in artificial or synthetic jewel making were performed in Dr. Aisen's student days in the University of Paris. One day Prof. Henri Moissan, his instructor and world famed chemist, found diamond crystals in the meteor. The meteor was one which had fallen in Arizona and was shipped immediately to the University of Paris for examination. Out of the discoveries of the pure carbon or diamond crystals that the meteor contained, conclusions were formed that it was chiefly a combination of heat and pressure that made jewels.

Dr. Aisen at this point became deeply interested in gem making; and analysis of the component minerals in various jewels followed, including various tests as to the proper application of heat and pressure. In his laboratories Dr. Aisen has formulas which can produce almost all known jewels and semi-precious stones, the only exceptions being so far the diamond.

After a gem has been analyzed and its component minerals found, the same proportion of ingredients assembled and put into crucibles where they are raised to the required temperature and then are suddenly cooled. There are a number of methods used to obtain the desired high temperature necessary in this marvelous twentieth century work. Among the first is the oxygen-hydrogen flame. Various types of electric furnaces are now used and (Continued on page 354)
Deep sea diving machine designed for use in raising torpedoed vessels was tested in Long Island Sound off New Rochelle, N. Y., recently. Its inventor, W. D. Sisson, has asked for a Government trial.

The machine, propelled by an electric motor, went down ninety-eight feet, bored holes in a steel plate, inserted rivets and brought the plate to the surface. It was manipulated by two men inside. The current was furnished from a barge. Its inventor asserts that the machine can be used to fasten water filled pontoons to sunken ships. Then, when the pontoons are emptied, the ships will be brought to the surface.

Propellers on the bottom for moving up and down and two on the side for propulsion communication established with the barge. The telephone operator on the barge manipulates the necessary switches.

**ELECTRICAL RESISTANCES AT LOW TEMPERATURES**

By Harry E. Dey, E. E.

The resistance of all pure metals to the flow of electricity decreases in proportion with the temperature, until at the absolute zero, (minus 273 Centigrade) *there is no resistance*. If it were possible to extend wires to the space beyond our atmosphere, which is supposed to have a temperature of absolute zero, unlimited power could be transmitted from any one portion of the earth to the farthest point away on the film of wires and without loss, excepting on the project is capable of a development of 225,000 k. w.

**HE DUCKED THE LIGHTNING!!**

Olympia, Wash., is some speedy place—If you don't believe it read this!

"Lightning struck in the same place twice in 30 years when it destroyed the home of Mrs. D. G. Parker, on Eastside street," says a "special" dispatch to a local paper of that city.

"A neighbor climbing down an adjoining cherry tree managed to duck the flash. Fire followed that burned the Parker house. Mrs. Parker escaped without being stunned." Well! Well!

**NEW MEXICO RADIO STATION**

There has been established a new Mexican Wireless Station on the island of Lobos, off the coast of Tampico, erected mainly for the purpose of affording facilities to the various petroleum companies for communicating with their vessels over great distances at sea. This station is said to be provided with some of the most powerful apparatus available, and is expected to establish communication with the Wireless Stations at Mexico City, Tuxpan, Tampico, Vera Cruz, Progresso, Frontera, Mazatlan, Santa Rosalia, La Paz, Queretaro, Monterey, Saltillo, Torreon, and by way of Havana with various stations in the United States.

With wireless stations powerful enough to reach vessels in all of its waters, the Chinese government will establish a typhoon warning service.
The motion picture dramas seem to be filled with scientific features now-a-days, especially in connection with German spy plots. To begin with we have the big patriotic film serial “The Eagle’s Eye,” from which we show photos of three episodes. The first is the adventure of “The Brown Portfolio.” The greatest single discovery which has been made in connection with the investigation of the Imperial German Government’s spies and plots in America, came to shadow him. At the time the United States and Germany were maintaining friendly relations, sincere on the part of the Washington Government, but absolutely hypocritical as far as the Kaiser’s representatives were concerned.

So the operatives assigned to Dr. Albert merely watched him, noted his visitors and his daily routine. Everywhere he went there was an indistinguishable shadow always with him. Dr. Albert lost his portfolio because he was aroused from a doze by hearing his station called by a guard on the elevated train on which he was a passenger. He forgot the bag for a moment, and his “shadow” got possession of it.

"Doctor, if thru your carelessness those papers have fallen into the hands of the Secret Service,” the German Ambassador exclaimed, “then steps will have been taken to warn the ships which are already upon the ocean, on which bombs have been placed. Arrange to have wireless warnings intercepted.”

The Ambassador walked from the room to his own private suite. Dr. Albert seized the telephone, almost distraught. He called Captain Boy-Ed. A second call apprised Captain von Papen of the disaster. A third telephone number and Heinrich von Lertz had been summoned to do the bidding of the arch spy—the accredited Ambassador of their automobile proved unfaithful and a skid in rounding a corner wrecked the machine against a bridge (see Fig 1).

Next we have the big “Munitions Scandal.” French soldiers on the first line in France were saved from a merciless assault from most German troops at a time when the French artillery would have been useless, by the alertness of the U. S. Secret Service. Members of the Kaiser’s spy army in America had successfully started on a plan which would have made a large shipment of artillery shells of every calibre for the French artillery useless because it would have been of a size which would fit only German guns. The specifications for the manufacture of the shells had been changed, when a trivial matter of the name of the ring-leader in the plot (Continued on page 356)
STOPPING an aerial raid by means of anti-aircraft guns is a notoriously impossible undertaking. While the aeroplane itself is now, and probably will always be the most trustworthy means of combating enemy bombing planes, there has been felt for some time the want of other means to bring down the raider.

We must not lose sight of the fact that a large city like Paris or London requires hundreds of the very best fliers as well as machines to safeguard these cities. These fliers could be used to a tremendously better fire of the boche protecting anti-aircraft guns below.

Nevertheless our pilots brave his barrage and fly right thru it. They "slip," nose-spin, loop-the-loop or "pancake," making it almost impossible for the gunners to get the range. If the pilot knows his business he returns invariably to his aeridrome, barring a few holes in his wings or in the fuselage of his machine. For be it known, there is no greater disgrace for a flier than to be shot down by land guns.

If we had a positive means to bring down erratic flight of such a device made it extremely inefficient, it was soon given up and came into disuse.

In the present device the writer proposes the use of a "mother-shell" containing two explosive bombs, as well as two "liquid-fire" bombs. Each one of these bombs has a smaller companion—a heavy lead ball, the purpose of which is explained later.

All of the bombs and balls are normally housed in the metal mother-shell which need not be very heavy, as it does not contain any explosive charge itself. All the bombs

purpose at the front hunting down Hun planes, while the former are kept locked up indefinitely to ward off enemy bombing squadron.

Anti-aircraft guns firing shrapnel do not bother an intrepid flier in the least nowadays. It frequently happens that a pilot must fly as low as 2,000 feet in order to successfully set into flames a boche "Drachen," as the German observation balloons are called "Over There." These aerial missiles are fired upon at close range by the Allied pilots, who use incendiary "phosphoric" bullets to accomplish the purpose. To do so they must fly low which immediately draws the

a raiding flying machine without utilizing our own or our Allies' aeroplanes, we would, of course, have the enemy at a great disadvantage.

Bearing these things in mind, the writer advances a plan which to a certain degree accomplishes such a result. The principle itself is very old and well known, the application and the various refinements only being new.

In short the idea centers itself upon the time-worn "chain-shot," which was nothing else but chaining several cannon balls together and shooting them at the enemy with devastating results. As the

are kept in their respective places by means of a casing composed of eight pieces of reasonably thin steel. These pieces are released from the mother-shell, and fly off as soon as the time mechanism located at the apex of the mother-shell permits this. This time mechanism works on the principle of the one used on shrapnel, the purpose of the present device being to keep the mother-shell intact till it comes within a few hundred feet of the aeroplane under attack. This, of course, makes for great accuracy, as the mother-shell can be accurately timed, and being a self-contained shell like any other, its flight will naturally be true.
ELECTRICAL EXPERIMENTER

To prevent the aerial lasso from causing widespread damage thru fire or explosion, should it miss an aeroplane, the four bombs can be equipped with time fuses, exploding them, before they reach the earth. Of course, the four lead balls might cause damage, but it is no more than the myriad of shrapnel balls and shell fragments, crashing to the ground during an aerial barrage.

The aerial lasso built on a smaller scale could, of course, be used between combating aeroplanes. If our planes were equipped with them, as well as our opponents, the Boche planes certainly would be at a terrible disadvantage.

NOTICE

With the September issue nearly every magazine which heretofore sold for 15c goes to 20c. This includes every prominent scientific and technical magazine. The price of the "Electrical Experimenter" for the present remains at 15c.

Altho tremendous pressure is being exerted upon us from all sides, due to soaring prices, we will not raise the price of this magazine at present. Paper alone has advanced from $5.00 per pound three years ago, to 11c a pound now, with printing, postage, engravings, art work and labor increased proportionally.

No other scientific Journal gives as much for 15c as the "Experimenter." All other magazines in this class print the more expensive. Ours is printed in eight point type:

This is ten point type.

This is eight point type.

Note the difference. "Experimenter" pages contain 30 per cent more matter, space for space, than the other magazines. Your 15c spent on this Journal really buys more than the 10c spent on other magazines. And we believe the quality of our matter is much above the average. Won't you show your friend this copy, or tell him about it?

The Publishers.

WHAT IS HIGH SPEED?

One of the first questions the layman asks the aviator is, "How does it feel to fly?" by which is generally meant, what is the sensation of speeding thru the air at the rate made possible by the aeroplane. The following account of the experience of a man appearing in Flight should be enlightening:

An analysis of sensation is always interesting and might be expected to be exceptional so in the case of speed, yet paradoxically enough there is no such thing as a sensation of speed. There are many sensations to which we are not conscious of, e.g. that the early centuries of human existence man, tho he has since been proved to be moving thru space at the prodigious speed of 50,000 miles per hour, thought himself to be living on the immobile hub of a rotating dome of the moving planets and stars.

What then is it that we feel when we are moved rapidly by an aeroplane? The answer is the illusion of speed, inspired by the sensation of acceleration which we have the habit of associating with rapid motion. This illusion can easily be induced without the aeroplane. For example, when a rocket is launched, for example, at one of the Earl's Court exhibitions a passenger trolley on a few feet of rails was arranged at the centre of a room of which eight steel rails were mounted so as to be bodily rotated round the trolley. The trolley was given a little jerk to convey the impression of a starting acceleration, and then as the trolley became stationary the room was made to turn at an increasing speed round the exponenters, who suffered from the conviction that they were traveling on smooth rails at a high speed.

Our impression of speed is derived largely from the optical effect, due to adjacent objects flying by, and is increased by a surface or skin effect due to the wind which brushes past us and cools and presses on to our periphery an atmosphere of sufficient, but the impression is heightened by going a little further. Our past experience of other mechanisms of the animal means by which we have borrowed speed has shown us that they are rare if ever perfectly smooth in their action. After the change of the sense due to the slightest noise, there are slight irregular changes of speed and changes in the direction of the movement. These are always associated with rapid traveling; we can dream jolts and jar. We are severely, and we wrongly regard them as part of the sensation of speed, tho they are pure accidents. They ought properly to be called accelerations, and the act of starting is the only acceleration which is in fact necessary to obtain speed. Yet a forward pressure can be derived from our impressions of speed. I allude to noise, whether of whistling wind or of beating hoofs or of moving machinery. These things have no more to do with the sensation of speed than the bristles constitute a hedgehog. They are merely excrescences and causes of independent sensation. At one time or another an aeroplane elicits a surprise to all these sensations to an acute degree, and super-adds one novelty, that of the speed of view.

The following comparative table of speed is of interest:

French electrical works have arranged to employ men who have been blinded in the making of electrical instruments after the system of Dr. Schuyler Whipple in New York. It is also understood the system will be introduced in England.
New Electrical Ideas on Submarines and Torpedoes

The busy war inventors have been bombarding the Patent Office at Washington with hundreds and even thousands of new and ingenious ideas on improvements in submarine warfare. Some of the latest endeavors of Yankee inventors to the study of submarine warfare science are here illustrated and described.

The first idea represents what its inventor—August S. Trautman—prefers to call "a submarine commander's observation and navigation contrivance." His invention, purports to provide a combined life-saving and observation chamber which is normally housed within a suitable compartment on board the submarine. When the submarine happens to become disabled thru a naval engagement or otherwise, or in the event of a fire, the commander of it should want to ascertain whether any enemy war vessels were in the immediate neighborhood before rising to the surface, it then becomes possible to have an observation officer enter the buoyant chamber shown, thru suitable water-tight doors, when the buoy chamber is opened. When the buoy rises then rises to the surface.

The buoy is at all times under control by the submarine by means of a steel cable attached to the bottom of the buoyant chamber and at the other end to a motor-driven windlass on board the submarine. A telephone and electric light cable is also unreel from the buoy as it rises to the surface, so that the observation officer can at all times communicate directly with the commander below.

As the inventor points out, his device can be made large enough to hold several men instead of but one, for the purpose of saving the crew's lives in an emergency. It is all difficult to arrange the apparatus so that the life-saving buoy could be hauled down to the submarine several times in order to remove all of the crew in case of disaster. The buoy could be designed sufficiently strong and provided with a sufficient length of cable to enable it to rise thru a depth of water of two hundred to three hundred feet.

As the illustration shows, the observation buoy is fitted with telephone and electric light and as well as this it is also fitted with firing guns, photograph apparatus, binoculars, etc.

The floating compartment is provided with suitable gyroscopic apparatus driven by an electrically operated motor to stabilize it, and there is also provided a means whereby the center of gravity of the buoy can be changed if necessary, so that the gyroscope might prove inactive.

There is furthermore a propelling mechanism driven by a motor and so designed as to cause the buoy with its occupants propelled in a body of water and beneath the surface thereof, and to be guided according to the desires of the operator. The cover of the buoy may be camouflaged so as not to become readily detectable by the enemy.

An oxygen tank is fitted within the buoy for the purpose of supplying the occupants with oxygen during the time that he is confined therein, and also a reserve tank is provided whereby air which is outside may be collected and accumulated. A motor-driven pump is provided to operate the auxiliary air apparatus. The buoy is fastened to the vessel by means of a suitable rudder provided at the base of the structure.

The second idea here illustrated is that of Mr. Seymour for what is called a Dirigible Torpedo, its inventor being James M. Seymour, Jr. Mr. Seymour, provides considerable food for thought in his novel invention which comprises an electrically driven outer hull, the interior of which is subdivided into a number of separate chambers, each one of which is adapted to house the various electrical contrivances and apparatus for controlling the torpedo. This steel hull is normally submerged beneath the surface of the water, and is designed for a depth by means of a surface float which carries visible identifying means, such as colored flags or disks in the day time, and signal lights flashed several minutes as well.

In brief, Mr. Seymour's electrically controlled dirigible torpedo is of the self-propelled type, being provided with a special contrast the high engine. It is equipped for one apparatus may operate when the torpedo is under way as a dynamo, supplying current for charging storage batteries, etc. Fuel for operating the engine is contained in a suitable storage tank in the torpedo hull, and also the supply of gases ready for mixture to produce the fuel for the engine.

This device is intended to be controlled thru a fine electric cable connecting it with a war vessel operating in the vicinity. The cable being of small size is stored in the hull of the torpedo, and is wound in an ingenious manner so as to be released rapidly and easily and without danger of knotting. The inventor's design enables a very long insulated electric cable to be used for this purpose (with its consequent high electrical resistance) for the reason that the device, when projecting, will be actuated by relatively weak electric currents coming thru the cable. The front end of the torpedo hull contains a storage tank for the engine or other charge, which can be detonated at any desired moment by simply pressing a button and releasing a kind of a gun or other vessel controlling the torpedo. It may be a surprise to the reader to learn that this small yet destructive war device may have a field on the ocean surface. To twenty miles, this being the radius over which the torpedo can be sent, and a sufficient length of the cable carried therein for the purpose of being brought up for the torpedo is placed over the side of the vessel, the engine self-starter motor is set in motion by means of a pull cable running up to the top float and fastened to a button thereon.

The third electrical idea is an interesting Cable-Cutting Shears, intended to be mounted on the bow of a vessel or similar war vessel. As is well known, it is a slow job for mine-sweepers to trawl along thru minefields. A way of adapting the cutting of the submerged mine-cables and the shears are provided with large blades, which in this manner cut through the end by means of a suitable rudder provided at the base of the structure.

The invention of Mr. Seymour is particularly intended for use in machine shops.
NEW ELECTRICAL IDEAS ON SUBMARINES AND TORPEDOES

(For full description see opposite page)
DETACHED reference to this subject-matter may be found in my book, "NEW CONCEPTS IN DIAGNOSIS AND TREATMENT" where attention was first directed to the demonstration of these phenomena by apparatus not available to the laity. Telepathy is in disrepute and the scientifically minded psychologist doesn't believe it. Science demands that phenomena should be objective, capable of reproduction at all times and demonstrable by instruments of precision. The simple scientific method which I shall present shows that spiritistic phenomena are independent of disembodied spirits and referable to human energy: that it will serve as a means of dissecting the occult and will enlighten the genius of the multitude in corroborating my original investigations.

We anticipate that this article will create a sensation in scientific circles, as well as with laity, and we present it for what it is worth. We have not made any of Dr. Abrams' tests, and we print the article with an open mind—neither endorsing nor condemning it. We say with Shakespeare: "THINKING THINGS IN HEAVEN AND EARTH, HORATIO, THAN ARE DREAMT OF IN YOUR PHILOSOPHY."

Dr. Abrams is well known as a scientist; he has made this interesting subject his life work, and his views are endorsed by many prominent doctors and scientists. He is the author of numerous works, amongst them an elaborate book: "NEW CONCEPTS IN Diagnosis and TREATMENT."

Will our readers please advise us should they be successful with Dr. Abrams' experiments?—The Editors.

TECHNIQUE.—The perciptent must have a regular and comparatively large pulse and preferably be seated facing the geographical West. Colored wearing apparel must be avoided by agent and recipient; the eyes of the latter must be closed to avoid distraction, breathing regular and mind abstracted during all observations. Experiments should be executed primarily in daylight. All reference to the pulse refers to the movements of the straw connected to the perciptent's pulse. Find the latter (Fig. 1) and indicate its location with a pencil.

Cut a very small piece of adhesive plaster and roll it so that the roll presents an adhesive surface on both sides.

Fig. 1.—X indicates the site of the wrist-pulse.

Fix it parallel to the pulse. To the plaster attach one end of a very fine straw (from a broom), 3/4 inches long. Place the straw at an angle so that it will approximate a segment of ruled paper (vertical lines).

Fig. 2.—Position of arm with straw attached to the pulse.

Observe the swing of the straw directly or indirectly. In the latter event, if the light is from the South use the right and if from the North, the left pulse.

Note that the greatest amplitude of the straw is secured by the arm resting comfortably on a book or cushion with the hand dependent from the side of the table (Fig. 2).

EXPERIMENT I.—Solving the mystery of mind acting upon mind by brain waves traversing the ether.

Prove that the brain waves are correct despite the fact that, telepathic effects unlike other forms of radiant energy do not vary in intensity according to distance. The moment a person (agent) WILLS FORCIBLY (not mere thought) there is a slight hesitancy or retardation of the straw. Close observation shows a slight extra kick of the latter followed by a transitory stop (inhibition). Each time the agent wills in the direction of the perciptent (irrespective of distance), the pulse effects may be noted. Before each act of willing by the agent, at least 10 seconds must elapse to permit the perciptent's heart to recover from the excited reflex. The latter is easily exhausted by too much experimentation on the same subject. If several persons are present, their minds should be passive so that the waves from the agent alone will act. Note by the effects on the pulse that some are able to will more forcibly than others.

"Over There"—A Miniature War Panorama

By GEORGE HOLMES

REALISTIC and beautiful is the presentation of a great Spectacle or Panorama in the miniature, when correctly staged. This field presents a wonderful opportunity for the real genius and creative mind to bring forth truly enchanting effects of color, scene and action. A splendid example of this fascinating art may be witness in the new and timely panorama "Over There" now being presented at "Luna Park"—the far-famed heart of Coney Island, New York City's pleasure ground. To say that Luna is pre-
sening it spells its success and from all accounts it bids fair to equal in fame if not exceed the original battle panorama of "The Battle of Waterloo," done by Robert Barker, or our own "Battle of Gettysburg." The creator of "Over There" is Mr. Hugh Thomas, for years associated with the big Coney amusement resort, projector of the "Submarine Battle," and other mammoth indoor spectacles.

There is a value about the panorama which cannot be denied. First of all, it lends itself only to subjects which are in-
a serious history away from its uses as an amusement proposition will come as news. Yet its initiation is connected with no less a personage than Sir Joshua Reynolds. The invention, for it was originally patented as such, came from the brain (Continued on page 353)

PUSH BUTTON—DYNAMO SPINS—LAMP LIGHTS!

Flashlights are now used by the million all over the world—practically every well equipt soldier in the Allied as well as in the German armies, not to mention the navies, carries an electric flashlight. Think what it would mean if overnight a modern Aladdin should wave his magic wand and decree that the flashlight could stay but that the batteries must go. Such will be the magical change which will overtake us one of these fine days when the invention illustrated herewith is successfully exploited and made cheap enough to be available to every man, woman and child who have any use for flashlights.

The model of the push-button dynamo flashlight shown herewith is somewhat large as it is the first model constructed by its inventor. The principles on which it is designed are, however, correct, and it is only a matter of refining the details of its make-up in order to reduce its size and weight. As herewith illustrated, the trigger which is placed on the handle and resembling that of a revolver, is successively pulled toward the handle by a natural gripping action of the hand, and this trigger works a quick-acting worm or screw similar to that found on the well-known ratchet screw-driver. The other end of this trigger actuated ratchet is mechanically connected with a small alternating current dynamo or magnet, which supplies the necessary current to light the flashlight bulb. The bulb is mounted in the usual reflector and furnished with a suitable lens.

Several years ago a similar dynamo flashlight intended to be operated by the pressure of the hand or fingers was brought out in Europe, but due to the war conditions which followed soon after its introduction, it has never reached the United States. The type of dynamo flashlight here illustrated was invented by a Yankee genius and the model was thoroly demonstrated before the editors.

WONDERS NEVER CEASE

"The Office Dog" conducts a full page feature in the amiable Ladies' Home Companion. It is usually a very bright page and you can learn a lot from it. We like it. Dogs, however, are notoriously shy of electricity, as any boy who has a spark coil and a dog will readily testify. Dogs and electricity never mix. "The Office Dog" is no exception to that rule. He is shy on electricity too! Witness the following blossom plucked from its May, 1918, page:

"Walking in a thunder storm under an umbrella with the modern metal rod is now said to be about the most danger-ous of practices, since the metal is an almost certain conductor of electricity. The italics are ours. It was a new discovery to us, that a metal could be an almost certain conductor. Will the "Office Dog" please send us at once a sample of that remarkable metal for analysis? Will gladly send him in return an almost certain soup-bone, guaranteed to give almost certain food for thought!"
The Man Who Stayed at Home

At last! A war play without "fire-works." To say the least, our American audiences of his sweetheart, which further adds to all the troubles.

have been bombarded with a class of productions and films that tended more to the "flag-waving" and "patriotic airs" variety, than to any real semblance of plot, story or genuine interest; which would in a moderate way serve to amuse, thrill and most of all, go a long way in the moulding of opinion and stir one to real conscientious and patriotic thought.

The production in mind was presented originally under the title of "The White Feather," by Mr. William A. Brady, at the Comedy Theatre in February, 1915. This was of course before we Americans had begun to think of a war with Germany or the intrigues that were taking place daily right in our very midst. Naturally under such circumstances, the most part of us, self-centered, failed to see the moral in the piece and like many other unfortunate plays it was relegated to the storehouse.

The story of the piece has had some material changes made in it, in that now it is the American troops and their transports which must be protected from the under-sea sniper the "Hun Submarine."

The action takes place in an English coast town. Mrs. Sanderson and her son are running a boarding house as a blind, being actively engaged in spring for the Imperial German Government. Christopher Brent, an Englishman of dense or "Silly-Ass" type, is a boarder. Everyone upbraids him for being a slack; even his best girl is doubtful of him. Naturally he feels very hurt but can offer no defense on his behalf for his seeming idleness because he is a spy in the employ of the British Government! With him at the same house is his "cryptic" and beautiful female aid in the person of Miss Miriam Lee. His being so much with the afore-said personage raises rebellion in the heart.

Nevertheless, and in a truly melodramatic style, he discovers the Hun's secret wireless outfit in the fireplace and turns it to his own advantage and then wrecks it. Further thrills are experienced in the attempted burning of the house and his almost untimely end in which he puts one over on the Kaiser's spies and their final round-up.

Whereupon he wins his "lady-fair" and the glory of the whole household, even to Dad's profuse blessings!

U.S. X-RAY STATION ON WHEELS.

For operating between the field hospitals and the firing lines, a Chicago electrical genius, Mr. C. L. Fitch, has developed the complete X-ray equipment illustrated. It is mounted on an automobile and derives its power from a specially designed direct current generator, driven by the engine. This generator is equipped to deliver 2 K. W. alternating current.

The transformer will deliver a spark from 10 to 12 inches long. The transformer and synchronous motor are mounted rigidly in a cabinet. The X-ray machine is of the interrupterless type, which is superior to ordinary machines which rectify their own current in the X-ray tube.

The marble switchboard has all necessary instruments such as a time switch, pole indicator, rheostat, pilot lamps, fuses, and switch; also a volt-ampere meter for the low tension side of the transformer. On top of the cabinet is mounted a milliamperemeter for measuring the current which passes thru the X-ray tube.

The Radiographic table is full size and can be tilted 90 degrees. It is equipped with one X-ray tube under the table for Fluoroscopic work and one above for Radiographic work. The lower one moves in a longitudinal direction, while the upper one moves both longitudinally and vertically. The table has an automatic tray and cassettes (plate holders) into which the plates can be inserted from the side.

As the cabinet is built in sections locked together, it is very easily taken apart and set up with the radiograph table together in a room or inside a house. In this case the automobile would be the power station and a cable would make the connection from the dynamo to the transformer.

In the left corner of the compartment is an instrument cabinet. In the bottom of this cabinet is a lead-lined cabinet for unexposed X-ray plates. Between the X-ray cabinet and the instrument cabinet is a dark room chamber which enables the operator to load the cassettes and to develop the negatives.

On the left side opposite the radiographic table is a leather upholstered seat which folds back into the wall. Occasionally it may be used as a berth. The room is lighted with white and blue electric lights. When the doors are closed it makes a very desirable dark room for Fluoroscopic work.

The Blind Now Tape Electric Coils

A SHORT time ago the question of securing some help from the blind was taken up by the Westinghouse people with the Pennsylvania Association, a branch of which is located in Pittsburgh, and a sample lot of motor coils to be taped was sent to the Association in order that the employees might be given a chance to show what they could do. When the coils were returned, it was very evident that this work could be done in an entirely satisfactory manner by those who have been deprived of their sight. Accordingly, arrangements were made with the management of the Association to allow some of their employees to do this work, payment to be made on a piece-work basis.

As this was an entirely new line of work for them, it was decided to have a representative of the Association go to East Pittsburgh to become familiar with the work so as to be in a position to instruct those assigned to do the work. The representative selected for this training was the wife of a former Westinghouse employee, who was deprived of his sight last summer, and who is now employed at the Association. She went to East Pittsburgh and was employed until such time as the management felt that she was sufficiently proficient in the taping of coils to teach the blind and to inspect their work.

At the present time seven persons are employed and their efforts have been very satisfactory, insofar as quality is concerned.

THAT ODD PHOTO!!! IS IT AN ELECTRON?

I was taking a picture of the Mess Hall at the New Trier High School, Winnetka, Ill., with the aid of a flash-light, writes Mr. Lytton Calrow, who submits this very interesting photo in the monthly “Odd Photo Contest.” At first we thought Mr. Calrow had really photographed a wild electron shooting thru a more or less tame molecule. But we were in for a bump. Listen to what the contributor has to say:

The flash-light powder was placed a little in front of a line with the lens and the results are noticed. I have seen several well known instructors in Physics and Chemistry and Optics and none could give me a definite answer as to what the reason for the lines and perfect elliptical figures were. They must be either grains of powder or light waves, it seems to me.

THE ETCHOGRAPH MARKS DESIGNS ON STEEL.

A small portable electric outfit, which can be used to mark small tools and for marking on any steel surface, has recently been perfected. The outfit consists of an electric pencil or “etchograph” and a step-down transformer which can be connected to any lighting socket. To operate the device, the electric pencil is drawn over the steel surface of the work, when great heat is developed at the point of contact due to the high resistance of the iron or steel. The etching depth can be controlled by means of a rheostat. The pencil used, it is said, can be handled with the same facility as an ordinary pen or pencil, and script writing or any other type of lettering can be used. The outfit is made to operate on 110-volt 60-cycle circuit, or can be used on 110-volt direct current with a small rotary converter.
New Electric Fuse Lighter for Blasting

A California inventor, Mr. Albert S. Cole, has devised a clever and very useful form of fuse lighter operating on electricity supplied from a battery. Where considerable blasting is to be done, it would seem that this apparatus would find extensive favor. The complete electric fuse igniter can be conveniently carried by a coal miner or other person, the battery, spark coil and so forth being enclosed in a small leather carrying case, somewhat resembling those in which binoculars are carried. With this apparatus a stream of electric sparks is obtained between the two metal points protruding from the hand electrode, whenever the battery circuit is closed by pushing the small switch button attached to this hand member in the manner illustrated. The spark coil may be one giving a 1/4 to 1 inch spark. The battery is made up of two or more dry cells, or several flashlight batteries can be employed instead. The stream of sparks obtained with this device serves to ignite the regular blasting fuse in the place of a match. It is possible to build the apparatus at small cost, and it possesses several unique features, one of them being that it is just as efficient on rainy or stormy days as it is on clear dry days, which is not the case when matches or other sources of ignition are employed.

HYDRO-ELECTRIC POWER VERSUS COAL.

The services of half a man are required in central steam stations for every thousand tons of coal used. Therefore the total labor required for the consumption of every thou-

sand tons of coal, on a basis of one year's time, is 2.78 men.

On the average, 1,000 tons of coal in the United States produce 125 h.p. for a year of time; 35,000,000 water horsepower developed and in commission would save the necessity of mining 280,000,000 tons of coal per annum. As regards labor, this vast tonnage requires for its production, transportation and consumption 280,000 x 2.78 men, or 778,000 laborers of one kind and another. The amount of labor required to operate this 35,000,000 water horsepower may be put conservatively at 40,000 men. Therefore the net saving in the way of labor alone by the installation of this water horsepower would be approximately 740,000 men for other industries.

HYDRO-ELECTRIC power is the real efficient energy of to-morrow.
Making Electricians Over Night

THE war has changed many things. If we were a speedy nation before the war, our national speed certainly has increased to a surprising extent ever since we entered the struggle. Year ago a German writer called America "the land of unlimited possibilities." His brothers are now finding out this truth to their hearts' content. Indeed, it seems as if there is no end to what we can accomplish, but if we are to win this war we must husband all our forces, not only in materials, but in human efforts as well. War economies are not only effected in wheat, beef or coal, but the saving of human time is an enormous factor if we are to win this war. It will not do alone to turn out 91 ships in one day or sending a million men to France six months ahead of the schedule. It is the man behind the gun who helps just as much to win the war.

If we can save a great amount of time for our workers we save just that much in dollars and relieve just so many more workers for other endeavors which we could otherwise not do. This was a book from three to four years to turn out an accomplished electrician who could be entrusted with any job that came along. Only a few years ago it used to cost thousands of dollars to make an accomplished electrician; which amount was made up in expensive tuition, board, etc., as well as money lost in non-production while the student was learning. Hundreds of thousands of dollars were lost in this manner because the student, seldom, if ever, is a producer while studying. This means a tremendous loss to the nation, as a minute's reflection will readily show.

However, nothing amazes us any longer in these stirring days. We are indeed doing the impossible in all branches of human endeavor. While we say today, "It can't be done," along comes a chap who has already done it and thinks it commonplace. Out in Chicago in the "I Will" city, they now have a big machine (which isn't patented, either), where they feed raw, lanky youths thru a hopper at the top of the roof and three months later full fledged electricians, with diplomas in their hands, walk out thru the school door ready to tackle any electrical job anywhere at a minute's notice!

This seems hard to believe when one stops to think how many things the student must learn before he can call himself an accomplished electrician. His knowledge not only lies in the theoretical learning, but it must include how to do things with his own hands. While the fundamental knowledge must be readily obtained from books, the accomplished electrician necessarily must know how to do things out of his hands, knowledge and will train him to do it in his own way, and unless he has the equipment to do it with it usually proves a long and tedious job.

The concentrated instruction necessary to turn out a modern electrician is being practised and it is quite amazing to see how quickly students become experts in nearly everything electrical in this school. In walking thru the instruction rooms we find students ranging from eighteen to fifty busy at work-practical work—in every conceivable branch of electricity. In one room we find a large number of students getting instruction in wire splicing. An instructor standing among them shows them just how it is done, explaining everything necessary, and then the pupils are taught how to splice the wire themselves. Here also they do soldering, testing motors and generators, while in other rooms we find them wiring lamps, telephone systems, lighting systems, as well as electrical sign systems. Next we see them at work on students getting instruction in wire splicing. There are also classes handling every kind of installation work.

The writer on a trip thru this institution watched students at work on meters, testing motors, transformers, alternators, driving generators, etc. He watched them winding stators, repairing arc lamps and doing all sorts of every day routine work on starting, lighting and ignition systems.

In still another room are seen students working on spark coils, as well as operating all kinds of motor control apparatus, testing watt meters and building switchboards.

It is quite surprising to find what a huge equipment is collected under the roof of a school of this kind, but on the other hand a minute's reflection will reveal that unless such a tremendous equipment was provided, no practical instruction would of necessity be faulty. As a matter of fact, if the students are bright and alert at all, they will themselves demand to see as well as do work upon almost any imaginable sort of electrical devices. The writer is quite certain that there was even an electrical locomotive upon which the students worked.

Besides teaching electricity the school also teaches practical draughtsmanship, and there are also plumbing and brick laying departments. Photographs Courtesy Chicago Covent Trade and Engineering Schools.

The Way to Learn Motor and Dynamo Winding is to Actually Do the Work With Your Own Hands, As This Student is Doing.

STATIC ELECTRICITY AND GASOLINE EXPLOSIONS.

Sometime ago there was much discussion by several authorities on whether static electricity resulting from pouring gasoline thru chamois could ignite gasoline or not. In connection with this an inquiry has arisen from a reader regarding static electricity when filling tanks, especially motor cars, with gasoline says a contemporary publication. This has been the cause of fires. In reply thereto, a Canadian Insurance Inspector reports as follows:

"The fire danger inherent in static electricity is present only when the chamois skin is used as a lining for the funnel or other filling apparatus. The use of chamois skin suggests itself because of the property of chamois to pass gasoline but to retain water."

"It has been found that when gasoline runs thru a metal funnel with chamois skin, static electricity is released which in a few cases on record has generated a spark and ignited the contents of the tank. It has been demonstrated experimentally that a spark is generated only when the funnel is held in midair, without making contact with the metallic gasoline tank itself."

"Since electricity seeks the shortest path, it is advisable to ground the chamois-lined funnel, by permitting it to make contact with the metal walls of the gasoline tank. This way all danger is avoided."

A case in point of the effect of the hazard of static electricity occurred on July 2nd when an auto truck of the Imperial Oil Company at its filling plant in Vancouver, took fire. The wagon was being filled from the tank and the driver had not made the proper ground connection, the tank being insulated by the automatic filling device. During the process of filling, static electricity was generated, making a small explosion which ignited the liquid in the tank truck.
Popular Astronomy
THE SUN AND HIS SATELLITES—THIRD PAPER
By ISABEL M. LEWIS
Of the U. S. Naval Observatory

Our sun is but a star traveling thru the universe at the rate of thirteen miles in a second. It is accompanied in this journey to unknown parts of space, that lie in the general direction of the constel-

Venus in Different Parts of Her Orbit as Seen From the Earth. The Direction to the Earth is Toward the Bottom of the Page. The Planet Mercury Shows These Same Phases. Neither Planet Can Be Seen When in Line or Nearly in Line With the Earth. Except on the Rare Occasions When They Transit the Sun or Pass Directly Between the Earth and Sun. When They Appear as Black Dots Projected on the Sun’s Disc. Usually They Pass Just Above or Below the Sun and Are Then Invisible. Due to the Glaring Light. Mercury is Never More Than 29 Degrees for Venus More Than 47 Degrees From the Sun.

lation Hercules, by an extensive family of minor bodies, the eight major planets and their encircling moons, twenty-six in number, one thousand or more asteroids, and numberless comets and meteors, all moving in prescribed paths around their ruler whose intense light and heat are the result of his comparative nearness. Seen from the distance of the stars he would be only one star among the hundreds of millions of stars that form the visible universe.

The most important members of the sun’s family are the major planets. Mercury, Venus, Earth, Mars, Jupiter, Saturn, Uranus and Neptune, named in the order of their distance outward from the sun. We hear occasionally of the possibility of the existence of inter-Mercurial and trans-Neptunian planets and some day an additional planet may be discovered within the orbit of Mercury or beyond the orbit of Neptune. The gravitational power of the sun extends far beyond the orbit of Neptune and there seems to be some evidence pointing to the possible existence of two planets on the outskirts of the solar system. The question of the existence of a planet within the orbit of Mercury is now, after long continued and diligent search, considered to be settled in the negative.

Were it possible to view the sun from the distance of the nearest star with the aid of the greatest telescope on earth all the members of his family would be hopelessly invisible. So, also, we cannot tell as we point our powerful telescopes at the stars whether these other suns are attended by planet families. We may only argue that it is very unlikely that there should be but one star among hundreds of millions that is attended by a group of comparatively small dark bodies that shine by the reflected light from the star they encircle.

With the exception of the two planets, Mercury and Venus, spoken of as the inferior planets, since their paths lie between the earth and the sun, all the major planets have moons or satellites of their own that encircle the mother planet just as the mother planet encircles the sun.

Saturn and its Three Concentric Rings Composed of Swarms of Moonlets in Revolution Around the Planet. Note Divisions in the Rings and Also Belts on the Planet Parallel to Its Equator.

Our planet earth has one satellite, the moon, that has the distinction of being the largest moon in proportion to the size of the mother planet. Jupiter and Saturn have moons that surpass our moon in actual size, in fact, two of the moons of the outer planets are actually larger than the smallest major planet Mercury but they are very small in proportion to the size of the planets around which they revolve. Mars, the next planet beyond the earth, the nearest of the superior or outer planets, has two tiny moons that bear the names of Deimos and Phobos. They are both less than ten miles in diameter and revolve very near to the surface of Mars. They can only be seen in very powerful telescopes. The inner moon Phobos is unique in the solar system for it makes three trips around Mars while the planet is turning on its axis or experiencing one day and night.

Jupiter the next planet outward from the sun is almost a sun himself in the eyes of his extensive family of nine moons. Four of these were first seen about three hundred years ago when Galileo pointed his first crude telescope at the heavens and any one can now see them with the aid of an opera glass. One of the four is equal in size to our own moon; the others surpass it in size. These moons are most interesting little bodies to observe and they have figured in some important astronomical discoveries as well. Their eclipses in the shadow of Jupiter, occultations or disappearances behind his disk, and the transits of their shadows as well as the bodies themselves in front of the planet are all phenomena of importance to astronomers and are therefore publish'd in the almanacs of all countries for every day that the planet is visible.

The free remaining moons have all been discovered in modern times. They are extremely small bodies visible only in large telescopes. Satellite V is the nearest of all the moons to Jupiter. The other four are at great distances from the planet.

The planet Saturn has nine moons, Titan, the largest, is nearly equal in size to Jupiter but is more than twice as far from the sun as Jupiter his moons are much more difficult to observe, tho the two largest are visible in small telescopes.

Saturn is unique in the solar system in possessing in addition to his nine satellites a most wonderful ring system composed of swarms of minute moonlets, each pursuing its individual path around the mother planet. It is this unusual ring system that makes Saturn the most interesting to observe telescopically of all the planets.

The planet Uranus has four satellites and Neptune one. Neither of these planets nor any of their satellites can be well observed on account of their great distance from the earth. The indistinctness of surface markings makes it impossible to determine the period of rotation of these two outer planets on their axes. It is believed to be very rapid, however, as is the case with the other outer planets Jupiter and Saturn. All the planets in the solar system fall naturally into two groups, Jupiter, Saturn, Uranus, and Neptune, the members of the outer group, have on the average, diameters ten times as large and therefore volumes...
one thousand times as great as Mercury, Venus, Earth and Mars, the members of the inner or terrestrial group.

The terrestrial planets are the pinnacles of the solar system, the outer planets are the giants. The density of the planets Mercury, Venus, Earth and Mars averages nearly five times that of water. One, at least, of these planets supports many varied forms of life.

The existence of life on Mercury is made impossible by the absence of an atmosphere. Venus and Mars both have atmospheres and there is a strong possibility that both of these planets may support life. Mars has probably been the most discuss of all the planets. The Venus, as the Earth's twin planet in size, mass, density, and surface gravity just as Uranus and Neptune are the twins of the outer group. It is generally believed that water and vegetation exist on Mars. The reddish color of this planet is supposed to be due to its extensive desert tracts. The existence or non-existence of certain surface markings on this planet, the "canals," still continues to be a matter of dispute. It is reasonably certain, tho', since air, water and vegetation exist on Mars that some form of animal life also exists there.

The question of life on Venus depends largely upon the length of its rotation period which is still uncertain since no definite surface markings can be found on this planet. So dense is the atmosphere of Venus that it appears to be always hidden from view beneath a canopy of clouds. It is the general belief that Venus, as well as Mercury, rotates on its axis in the same time that it takes to make a revolution around the sun. In this case the same side of the planet would always be turned toward the sun and under such circumstances life on Venus would be very difficult due to great extremes of heat and cold.

This peculiar form of rotation is by no means unknown in the solar system.

The Planet "Mars"—After a Drawing By Alfred Rondane, Made December 3, 1911. Note the Canal Lines. Which in the Larger Telescopes, Are Plainly Discernible.

Our own moon always keeps the same face turned toward the earth and the evidence seems to be that some of the satellites of Jupiter and Saturn rotate in the same way. The length of the day on Mars is known very accurately on account of the rareness of its atmosphere which enables one to make out surface markings. Its length is about 24½ hours and its seasonal changes strongly resemble our own.

Life on any one of the outer planets is impossible. The density of these planets averages about the same as the density of the sun which is a little higher than the density of but this view is no longer held. The asteroids as well as the comets and meteorites may represent the material of the primitive solar nebula that was not swept up when the larger planets were formed.

With few exceptions the asteroids are only to be seen in large telescopes and then only as star-like points of light. Most of them are simply huge rocks and all are necessarily devoid of life since such small bodies have not sufficient gravitational force to hold an atmosphere.

Law and order prevail among the different members of the solar system. The revolution of the planets around the sun and of the satellites of the planets around the primary planets are performed according to known laws that make it possible to foretell the positions of these bodies years in advance. Asteroids and comets also obey the laws of the solar system and after three observations of the positions of one of these bodies have been obtained their future movements can be followed. There is, moreover, a uniformity in the form and motions of the planets and their moons that is considered significant in connection with the origin of the solar system. All the planets and their satellites are nearly perfect spheres. They all, with few exceptions, rotate on their axis and revolve around the sun or, in the case of moons around their primaries in the same direction from west to east. When the noted nebular hypothesis was advanced to explain the origin of the solar system the exceptions were unknown. They are now considered to make doubtful the truth of the hypothesis. These exceptions are the two outermost satellites of Jupiter, the outermost satellite of Saturn, and the satellites of Uranus and Neptune. All these bodies retrograde or travel in their orbits in a direction opposite to that of all the other planets and satellites.

The paths of all the planets around the sun are nearly circular and they all lie in nearly the same plane. The asteroids have orbits that are more flattened or elliptical and these orbits are in some instances highly inclined to the planetary orbits. The comets have orbits that are usually very elongated ellipses or parabolas. Some of the comets may be only temporary members of our solar system the astronomers generally believe that they are all perman-
HAVING read with a good deal of interest Mr. Gernsback's articles in recent issues of the ELECTRICAL EXPERIMENTER in regard to winning the war by building a new type of machine called Gyroscopics, which would spread defeat and consternation in the ranks of the Hun, I beg to take issue with him on the feasibility of this plan, regardless of its astounding features:

In the May issue, he says editorially:

"This war, more so than any other, is a machine war. A stereotyped phrase, but, nevertheless, a very true one. When we speak of a machine war, we usually have in mind artillery of all calibres, from machine guns upwards to 42 inch breech-loaders. The enemy, he must fall back. Even trench systems without artillery support from the rear can not be held for any length of time by the enemy. If our artillery is intact, but if the enemy is deprived of his, even the hands of machines cannot compensate his ours ten to one, he would have to retreat just the same. These, of course, are very obvious facts."

According to reports from the fighting fronts this is true enough without the endorsement of the General Staff. In the next paragraph he writes:

"The British now engaged in the Western war theater realized this truth very early and set about to rectify it. The result has been the recent Tank attacks. These machines fulfill several purposes; they are used to batter down the barbed wire entanglements protecting the trenches; secondly, they raise havoc among the enemy's men by flank fire once across his lines, but most important of all, the Tanks are the enemy's artillery either by putting the artilleryists out of action by gun fire from the Tank or by climbing right over the enemy's guns, thus putting them hors de combat. For the first two purposes the Tanks are ideal; for the latter they have signally failed. The reason is very simple. The Tank is an extremely slow-moving vehicle in the open field—five to eight miles an hour at the most—is its speed. Even if camouflaged a Tank makes a shining mark for the enemy gunners, who find little trouble in hitting its size. The only crawling tractor. One or two shells soon puts the most ambitious Tank out of business."

And, in truth, he might have added, if the Tanks have any real military value where are they in the past big (Allied) drive? One would expect to read in the newspapers how the Tanks like bits of Gibraltar stood out in the open and stemmed the advance, but such has not been the case. There is the case of a battle in a war where nothing can live above the ground, and even steel and concrete project-

Gyroscopic put in the face of such a fire, with their limited crew and supply of ammunition, especially when the batteries of the enemy are capable of throwing up every foot of ground. A few well directed shells of the 42 cm. type would be sufficient to put them hors de combat without further ado.

Mr. Gernsback states:

"In other words, the large and speedy machine obviously is the thing in this war. In former articles we have shown that it is perfectly feasible to run monster machines over land at speeds from twenty miles upward."

Possibly, how would it be done in the mud of Flanders? The Gyroscopic with its heavy bulk would sink axle deep in the mud. Its success would depend upon dry ground and smooth ground at that. Even if it could succeed in passing the enemy's barrage and run down first line trench batteries and machine guns, it would still have its work cut out for several miles back to contend with as well as guns at a much nearer range, and would be practically blown to pieces before it could over-run them.

By this reasoning we are able to see that no machine of the Tank or Gyroscopic type can expect to achieve a decision in this war. It is in the air that we should look for results. Swiftly moving bombing planes which offer little target to the enemy can be depended upon to put the enemy's batteries out of business, no matter where they are located. As many military experts have stated the decision will be in the air. The side that controls the air will have the advantage. With thousands of bombing planes covering the Western front it would be impossible for the Hun to set foot on a bit of safe ground. With all the talk of the Allies devoting a large fleet of planes, it appears that very little has been accomplished in this direction. Because if they had how was it possible for Gernsback's work to spread such immense forces and materials on the Western front for the past spring drives.

According to the Tank and Gyroscopic defense idea, we wait until the enemy has assembled all his forces and munitions for the drive before they are called on for action. On the other hand, the bombarding plane checks the enemy while he is trying to assemble his supplies, by hunting out the most vulnerable points of attack. I can not believe that a suitable supply of bombing planes would make a big offensive impossible, by bombing everything above ground. Not only could these planes, by swiftly moving planes, capable of returning to a base of more and returning the bomber, the Tank and Gyroscopic could attain no such speed or return for supplies. On the other hand, this would mean that not until their supply of ammunition is used up and become the prey of the enemy.

While it is evident that this is a machine war, and the Tank has been tried and the Gyroscopic suggested, I am confident that the need will be accomplished with men, munitions and bombarding planes. Men and munitions, of course, are everything, but in addition to these, the practical value of the bombarding plane has been proved over the Tank and Gyroscope, and they will bring results unless some inventive genius brings forth some new type of land battleship. Nothing can escape these bombs; they are everywhere at once, carried by swiftly moving planes, capable of returning to a base for more and resuming the hunt. With the Tank and Gyroscopic the enemy's army can be destroyed and other means, one of which is the bombarding plane, must be found to overcome them.

LOUIS LEON.

Rochester, N. Y.

Leon Telegraph & Wireless School, Director Wireless Telegraphy, Mechanics Institute.

Mr. Leon's criticism is well taken, but I regret that I cannot agree with him. Quite the contrary.

My answer resolves itself into the one word: SPEED. In my article in the February 1918 issue of the ELECTRICAL EXPERIMENTER I stated explicitly:

"As we have pointed out before, what is wanted is a machine, not necessarily monstrous and weighing many thousand tons, but one that need not weigh more than the present Tank, and that can cover ground rapidly, so that it becomes almost impossible for the enemy to get the range."

I refer more specifically to the Gyroscopic, which I have also extended to the Gyro-Electric Destroyer, here illustrated, was fully described in our February, 1918 issue. This 450 horse power Monster is Steered by a Large Gyroscope Wheel, Shift ing the Latter Either to the Right or the Left, The Wheel Made of Lattice Steel Work Is Practically Proof Against Stray Shell Shots. The Destroyer Runs at a Speed of From 40 to 60 Miles an Hour and Due to Its Huge Diameter It Rolls With Ease Over Trenches and Other Obstacles.

The Gyro-Electric Destroyer, Here Illustrated, Was Fully Described in Our February, 1918 Issue. This 450 Horse Power Monster Is Steered by a Large Gyroscope Wheel, Shifting the Latter Either to the Right or the Left. The Wheel Made of Lattice Steel Work is Practically Proof Against Stray Shell Shots. The Destroyer Runs at a Speed of From 40 to 60 Miles an Hour and Due to Its Huge Diameter It Rolls With Ease Over Trenches and Other Obstacles.

"It should also be noted that only a very moderate speed of the motors is necessary; inasmuch as the diameter of the wheel—45 feet—is so large that it would be impractical to drive it at a rate of from forty to sixty miles an hour with the motors running at very slow speed."
ELECTRICAL EXPERIMENTER

Exactly as the Hun submarine is helpless against our fast moving destroyers—
for it can not get the range quickly enough —so the Hun gunner is helpless against our Gyro-Destroyer. And just as our boys
in blue drop a depth charge on the prowling U-Boat in Khaki drop a bomb on the German Gun.

Mr. Leon says: "How could the Gyro-
Destroyer run thru the Flanders mud?"
The answer is simple: it doesn't why

should it? Guns cannot advance thru mud
either, nor does an army as a rule. Both
contending forces, if mud separates them,
are deadlocked. But we can run over dry
land, and there is always plenty of that
somewhere, and we can then take the
enemy from rear and destroy his guns, before
he knows what hit him. Then if our infantry
follows the Destroyer there will be an
end to the deadlock in that section behind the
Flanders, or any other mud field.

Nowhere in my articles did I mention
that the Gyro-Destroyer could or would
win the war, but I did say:

"It is evident that a machine of
this kind should do as good work as a
thousand men in the field, and, perhaps,
last longer.

I still maintain that I am right, until
actual experience with such a machine
proves me wrong, and that I firmly believe
won't happen.

In connection with the above a curious
thing is happening of late. I am in receipt
of many letters from "Electrical Experimenter"
readers, telling me what they think of
the different articles. These letters are fair samples of the many
that come to my desk, but I will let them speak
for themselves.

Editor Electrical Experimenter:

In reference to your May Editorial
and some of the preceding ones. I
wish to state that I am totally in
sympathy with you as this "Monster
Land Battleship" is concerned. I am
well acquainted with the details of it,
as I have read your magazines as well as some of a few years ago
where you have also presented a
machine of that kind but of a different
construction. I do not agree with your
opinion in reference to the "Tanks" for
I have seen one and its clumsiness.
Now in order to let you may not appeal
in your Editorials without results
would suggest, that, being your cir-
duction reached the 100,000 mark, and
naturally all those who read the Elec-
trical Experimenter cannot but be
interested, should patriotically con-
tribute $1.00 to the Editor. The donor
should dispose of all such money by
building and perfecting one of those
Giants and prove to the Government its
effectiveness.

For the Government at the present
time is overburdened with the enormity
of its war tasks and it hardly has
time for experimentation.

I personally would be more willing
to make such a contribution and would urge it upon a wider circle.

You know how to reach the people who
should read your magazine.

JOSEPH SEAR,

(Cont. on page 347)
The Phenomena of Electrical Conduction in Gases

PART V—WEIGHING AN ION

By ROGERS D. RUSK, M. A.

The simplest method of measuring \( m \) is called the energy method of J. J. Thomson. It is a well-known fact that the energy of any moving body is \( \frac{1}{2} mv^2 \), and if this be the energy of one electron the total energy of \( N \) electrons is:

\[
\frac{1}{2}Nm^2v^2 = W
\]

which may be measured in terms of the amount of heat generated when these rays fall on a metal plate. But the number of electrons \( N \), is equal to the total charge \( Q \), divided by the charge on each electron \( e \), and the equation becomes

\[
m = \frac{2W}{eQ}\]

So when the heat \( W \) is measured, the quantity of electricity \( Q \) in the gas, and the velocity \( v \), are measured it is an easy matter to calculate the ratio \( \frac{m}{e} \).

There are many other ways of measuring the same quantity chief among which is a method depending on the fact that positive or negative ions may be bent by a magnetic force. As the magnetic force on the ion depends on the charge on the ion and as the amount the rays are bent will vary inversely as the mass of the ion, it is readily seen that the amount of bending can be measured in terms of these quantities and set equal to or the reciprocal of \( \frac{m}{e} \). Fig. 1 represents the deflection of ions by magnetism, in a tube similar to that used for measuring the velocities of ions.

Now to measure the mass of an ion or to weigh an ion all that is necessary is to find the quantity of electricity carried by each ion and substitute it for \( e \), in the quantity \( m \) divided by \( e \), then solve for \( m \) the mass.

The first step then is to measure \( e \), the charge on an ion, and this like other similar processes can be accomplished in several ways, but practically all methods for measuring \( e \), which have been developed so far depend on the fact that drops of water can be made to condense about ions and if sufficient ions are present a cloud is formed. It had been suspected for some time that the presence of dust particles in the air was one of the causes which made moisture collect in drops and fall as rain. In 1897, C. T. R. Wilson made the discovery that in dust free air clouds would form if electrified particles or ions were present. This discovery was immediately followed up by H. A. Wilson, J. J. Thomson and others, who made use of the new fact to enable them to determine the charge \( e \), on an ion.

As is well known the complete or total charge in the electrified gas can be readily measured by driving these ions by means of an electric field to a plate connected with an electroscope or electrometer. If the number of ions were known \( W \) would be a simple process to divide the total charge by the number of ions, and obtain the charge on each ion. Up until Wilson's discovery the counting of such minute particles as ions had been an utter impossibility. Now assuming by the laws of probability that only negligible number could form about two or more ions at the same time it was only left to count the drops and take this as the correct number of ions.

In order to insure as great accuracy as possible very small drops were used, and instead of being visibly counted their number was estimated in the following manner:

A single drop was observed in a microscope and its weight calculated from its diameter. Then the whole cloud was weighed and this total weight divided by the weight of a single drop. This gave the number of drops. The total charge was then measured as suggested above and divided by the number of drops. This was the charge on the ion, and two birds were killed with one stone for now the mass could be gotten from the various values which had been obtained for ratio of the mass and charge.

A typical apparatus for producing such a cloud is shown in Fig. 2. A is the expansion chamber and \( P \) is the pump by which a known expansion can be obtained; \( E, E \) are the electrodes. When the piston is pulled down the air is rapidly expanded and very rapid evaporation takes place (Continued on page 355).
**Experimental Physics**

By JOHN J. FURIA, A. B., M. A., (Columbia University)

**LESSON FIFTEEN**

**CURRENT ELECTRICITY**

(Continued)

**Experiment 87.** Place two test tubes with holes in their bottoms into a vessel of water (see Fig. 79). Fill two test tubes with sulfuric acid and invert them in the vessel as shown. Lead current from storage battery or other sources of at least ten volts to platinum electrodes $P$ and $P'$ (seed nails will do fairly well if platinum is not available). Bubbles of gas will appear rapidly, the negative electrode filling its test tube twice as rapidly as the positive. On testing we find that the gas at the negative electrode burns with a blue flame (a test for hydrogen). The gas at the positive electrode does not burn; but a glowing splinter when placed in the gas burns brightly, i.e., the gas supports combustion (a test for oxygen). **CARE MUST BE TAKEN WHEN MAKING THESE TESTS TO KEEP THE TEST TUBES INVERTED; OTHERWISE, THESE GASES BOTH BEING LIGHTER THAN AIR, WILL ESCAPE.** Modern theory explains this phenomenon, *electrolysis*, as follows: When the sulfuric acid is dissolved in the water, it breaks up into positively charged hydrogen ions and negatively charged sulfate ions. The current causes an electric field to be established in the solution between the electrodes. The hydrogen positively charged ions are attracted by the negative electrode and repelled by the positive electrode. On reaching the electrode their charges are neutralized and the ions combine and form hydrogen gas. The negative ions move to the positive electrode, their charges are neutralized, they react with the water liberating oxygen and forming additional sulfuric acid. The fact that we find that two parts of hydrogen are given off to one of oxygen is one of the reasons for believing that each molecule of water is composed of two atoms of hydrogen and one atom of oxygen.

**Experiment 88.** Just as water can be decomposed into hydrogen and oxygen, the elements in their right proportions can be mixed and water formed. Any of the methods can be used for securing the Hydrogen and Oxygen but the following is the simplest in which to secure and mix the elements in the correct proportions. See Fig. 80. The jar contains dilute sulfuric acid. Electrodes, thistle tube $T$, and J-tube, are connected thru a tightly fitting rubber stopper. MAKE SURE THAT THE J TUBE IS TOTALLY IMMERSED AND THAT THE "I" (TOP) TUBE IS NOT IMMERSED. The other end of the J-tube is immersed in a porcelain crucible or china cup containing a soap solution such as one uses for making good soap bubbles. When the current is turned on the solution in the J-tube breaks up into two parts Hydrogen and one part Oxygen, as in the previous experiment. The gases mix in the proportions in the space above the solution and pass out thru the tube into the soap solution forming bubbles of Hydrogen and Oxygen, each bubble containing two parts Hydrogen to one part Oxygen. The first few bubbles contain the air of the space above the solution and should be blown away. Then touch the bubble with a lighted match. A loud but harmless explosion will result (harmless because it is an inward explosion rather than an outward) and water is formed. The use of the thistle tube is obvious. Should the pressure of the gas in the jar become large because the gas is not escaping thru the J-tube as rapidly as it is generated, there would be a danger of an explosion and of the jar bursting. Instead, as the pressure increases some of the solution is forced up the thistle tube, making more room for the gas and also causing less surface of the electrodes to come into contact with the solution. This principle is extensively used in gas generators to avoid accidents. **Experiment 89.** Place a solution of copper sulfate in a vessel (See Fig. 81) AB and AA' and heavy copper wires insulated from each other and connected to a battery of at least ten volts (D.C. house current is very good) to wire $W$ is forced. The *positive wire* connect some pennies or other pieces of copper (a), (c) and (e); to the negative connect a key (b) a spoon (d) and a coin (f) (not copper). On passing the current thru, (b), (d) and (f) become copper-plated, the speed of the action depending on the current. In a similar manner by using silver instead of copper and a silver salt instead of copper sulfate we can silver-plate articles suspended on the negative wire. Wire can be carbonated and we have a nickel-plating and with gold and a gold salt we gold-plate. **SHOULD BE TAKEN TO CLEAN WELL THE ARTICLES TO BE PLATED.** The explanation is similar to that of electrolysis of water. The dissolving of the salt in the water causes the salt to dissociate into the positive metal ion (copper, nickel, silver, gold, etc.) and into the negative ion (sulfate, chlorid, etc.). The positive metal ion is attracted to the negative electrode because of the electrical field established, loses its charge and deposits itself (or plates). The negative ion passes to the positive electrode, gives up its charge and combines with the metal to form more salt which in turn dissolves (the sulfate ion loses its charge and combines with the copper to form copper sulfate, which goes into solution). Thus the strength of the solution is maintained and the metal at the positive wire is eaten up. **Experiment 90.** Electroplating is an important application of electroplating. Set up in common type the page to be electroplated. Stamp it in wax or other compound prepared for taking moulds. Coat the wax impression of the type with graphite powder to make it a conductor of electricity. Surround this at the negative electrode of a copper-plating outfit as described in Experiment 89. When a sheet of copper about 1/15 of an inch thick has been deposited on the wax mould, remove it from the solution and peel off the wax and replace it with a molten type-metal backing to give strength to the copper facsimile. From such an electrolyte many thousand impressions can be made.

**Experiment 91.** In the last lesson we learned that electricity in motion is always accompanied by a magnetic effect (Oersted's experiment) and that by using a right-hand rule for determining the direction of the magnetic field knowing the direction of the current. Let us look into this effect a little further. (Continued on page 359).
Notice to All Radio Readers

As most of our radio readers are undoubtedly aware, the U. S. Government has decreed that all Amateur Wireless Stations, whether licensed or unlicensed, or equipment for receiving or transmitting, shall be closed.

This is a very important consideration, especially to those who are readers of the Electrical Experimenter, for the reason that we desire to continue to publish valuable articles on the wireless art from time to time, and which may treat on both transmitting and receiving apparatus. In the first place, there are a great many students among our readers who will demand and expect a continuation of the usual class of Radio subjects, which we have publish’d in the past four years, and secondly, there will be hundreds and even thousands of new radio pupils in the various naval and civilicn schools throughout the country who will be benefited by up-to-date wireless articles treating on both the transmitting as well as receiving equipment. Remember that you must not connect up radio apparatus to any form of antenna.—The Editors.

U.S. Signal Corps Radio Outfit in France

The Radio Division of the U. S. Signal Corps has been wonderfully enlarged since our entrance into the great world war, and thousands of portable wireless outfits are being assembled and shipped to Europe at this time. The accompanying photograph shows one of the Signal Corps Radio Squads on duty in France. A collapsible telescopic mast is usually supplied with this apparatus so that the antenna can be raised or taken down at a moment’s notice.

When the troops are entrenched in dugouts, then the radio men install their apparatus in a well protected underground cavern and lead their antenna wires from the apparatus up thru dark passages and out to the aerial itself. In trench warfare the antenna is a low affair not extending over three to four feet above the trenches. The antenna under these conditions is given a fairly good length to make up for the low altitude.

When the army makes a rapid advance, then the radio crews move forward with the troops and carry their wireless apparatus and aerial paraphernalia on mules or horses, or still more often nowadays, on auto trucks, some of which are assigned to the radio divisions for the purpose. There are also a large number of portable wireless outfits mounted in auto trucks which can travel over the field very rapidly, and which can be put into operation in less than a minute. In some of these auto trucks are carried a telescopic aerial mast made of steel tubing, and are provided with special means for quickly raising and lowering the mast.

Quick Transmission of Telegraph or Radio Messages.

Altho there are 26 letters in the English alphabet only 23 are used frequently, the ones very seldom used are "X, Y, Z." As would be written "ston, lin, lim, practic, etc."

3rd Proposal: In such words as "Experi- menter, longer, water, writer, seeker, feeler, stronger, quicker, etc." I would eliminate the "e" before the final "r," and the words would then be written as follows: "Ex- perimenter, longer, wattr, seeker, feeler, strongr, and quicker." Also the "e" before "d" as "stored," etc.

4th Proposal: "X" at the end of a word would indicate "shun" as in "Induction, fiction, traction, fashion." The above would be written as "In- duct, flex, tracr, and fax." The "shun" in centers of words can also be written "Fax- able," as in "the end of a word would indicate "able." "Disabled, fable, table, etc." would therefore be written "Dzd, fzd, tz, etc."

5th Proposal: "Z" at the begin- ning would indicate "st" as in "stick, a t a y c d., stem, steamer, etc. They would be written as follows: "zick, zayd, zinc, and zeamr, etc."

"One of your Radio Bugs."

Four working parties building a railroad across Australia keep in touch with one another by wireless telegraphy.

American naval officers are installing a wireless telegraph station in France. The Temps announces that the station will be ready for use in August to correspond with the station in Annapolis. It will cost $2,500,000. After the war the station will be taken over by the French.
ELECTRICAL EXPERIMENTER

The line connection is used only in cases where it is desired to receive thru head receivers, in which cases the head receivers are connected by plugging into this socket. In the event that more than one pair of head receivers is to be used at a time, they may be plugged into a connecting cord and in turn connected to the line connection in the set. This set has incorporated in it a ballast resistance which makes it possible to connect any number of head receivers without interfering with the sound of the buzzer.

The set shown herewith is furnished complete with two three-foot cords for connection to the Battery and Omnipgraph, but does not include Battery, Omnipgraph or Head Receivers.

UNCLE SAM PAYS $1,600,000 FOR POULSEN PLANT.

The PoulSEN Wireless Telegraph & Telephone Company has sold its wireless rights and plant in the United States and dependencies to the U. S. Government for $1,600,000. This payment has already been made, while important deals are said to be pending for the sale of PoulSEN rights for use in other countries.

SWEDISH RADIO TALKS TO PALESTINE.

Sweden's most powerful radio station, situated at Karlsborg, has been put into operation. Regular communication is now being conducted with Dutch Altenburg in Austria, and also Tsrskoe-Selo. Messages have also been exchanged with Spanish stations and Constantinople. Word has been received that the Karlsborg station's messages have been read by a little station in Damascus, Palestine, although the Damascus station's plant is too weak to reach Karlsborg.

CRUFT HIGH TENSION RADIO LABORATORY.

The accompanying photograph shows the excellent building and lofty latticed-steel aero mast at the Cruft High Tension and Radio Laboratory at Cambridge, Mass. This laboratory which was built several years ago, was used as a special research laboratory prior to the declaration of war by the United States. It was formerly used by the U. S. Naval Radio School at Cambridge, but it is now directly used by this school.

The Cruft Laboratory was built to carry on high class wireless and allied high tension research work, including such measurements as the quantitative and qualitative tests of radio signals, the determination of the operating characteristics of radio transmitting as well as receiving apparatus, wireless telephone experiments and tests, etc. Considerable work has been done at this laboratory in the short time it has been in operation including a large number of experiments on the wireless telephone of Prof. Chaffee.

The laboratory is fitted up with a complete equipment of the various measuring instruments necessary for conducting tests along these lines, and constitutes one of the best equipped laboratories of its kind available today.

A CONSTANT TONE RADIO BUZZER AT LAST

For a hundred and one purposes the radio man daily finds that he needs a constant tone test buzzer. For all accurate measurements of wave length and decrement such a buzzer is absolutely essential. It has remained for a well known English concern to bring out such a buzzer, which sells for something like nine dollars, but it is worth it.

This instrument, the result of exhaustive experiments, will operate continuously at constant amplitude without changing its periodicity, and the note is instantly variable by the movement of a cam, say its sponsors. A pure musical tone with a range of three octaves can be obtained. Sparking at the contact points is entirely eliminated by a small graphite rod which can be shunted either across the coil or the platinum contacts, and if desired cut out entirely.
The Einthoven Galvanometer—
Its Theory, Operation and Construction

By SAMUEL D. COHEN

The electrical measuring instrument is the most important asset to the electrical and radio experimenter, and would be impossible for him to study the actual characteristics of any electrical piece of apparatus without the aid of it. Voltmeters, ammeters and wattmeters are the ones used to the greatest extent by the engineer. However, the most important of them all is the ammeter, especially when it is used to measure a minute quantity of electricity flowing thru a given circuit. This instrument in its finer term is called a galvanometer. A galvanometer is a delicate and sensitive electrical instrument used for measuring very small electric currents. To the radio experimenter and engineer, the galvanometer is found to be most useful, insofar as unimaginably small currents are dealt with, especially in the radio receiving circuit where currents of one-thousandth part down to a few millionths of an ampere flow.

Practically all galvanometers with which the student is familiar consist of two main parts, a coil of wire thru which the current can flow to be measured, and a permanent steel magnet constituting the field. This is the moving coil type. In other forms of this instrument, the coil is comparatively large and is rigidly fast to the frame of the instrument, while the magnet is a small piece of steel suspended lightly by a fiber of untwisted silk or quartz. In other galvanometers the arrangement is reversed, and the coil or part carrying the current is made as light as possible and placed in a very powerful magnetic field produced by a large electro-magnet, which usually forms the body of the instrument. The latter type of instrument is the one in which we are interested, as it has proven to be the most sensitive of them all.

Even in this class of galvanometer, there are two types, the one developed by Prof. Korn, who utilizes two, fine parallel wires suspended in a powerful magnetic field, and a second form devised by Prof. Einthoven, who uses a fine, single silvered quartz wire placed in an extremely powerful magnetic field. The latter was found to be far more sensitive than the former, and this type of galvanometer will therefore be described in this article.

Several years ago the author constructed a very simple Einthoven galvanometer. Although not as sensitive as the commercial ones, it gives fairly accurate results in experiments which are conducted in radio receiving circuits. The instrument was sensitive enough to record radio received currents from distant transmitting stations.

A commercial form of Einthoven galvanometer is shown at Fig. 1. Here A represents the powerful magnetic poles excited by the huge electro-magnets, B, B. The case, E, contains the fine wire carrying the current to be measured. Fig. 2 shows schematically the arrangement of the suspension for the fine wire E, which must be as fine as possible. Platinum, silver or aluminum can be used, but it was found that even a smaller diameter can be obtained by using quartz or glass fibers, these being platinumized or silvered. The ends of the wire are soldered to T-shaped members, which are held by two set screws placed at the ends. Adjusting the tension of the wire is a close operation and it is carried out by mounting the upper wire carrier upon a rod having a cam at the upper end, the rod being normally pushed up by a spring. With this arrangement a very fine adjustment of the wire is secured, connection being made to the ends of the wire.

The method of noting the displacement of the wire when carrying a current in the magnetic field is shown in Fig. 2. An eyepiece, AE, is inserted in a hole in one of the collars, F, G, of the poles, B, B. A telescope in this eyepiece can be used for registering the minutest deflections of the wire. The galvanometer is adjusted by moving the eye-piece up and down, as shown by the arrow I in the eyepiece. A telescope, however, may be used if more accurate readings are required. The number of deflections is counted, as shown at J, and multiplied by the number of divisions each deflection makes.
the magnet poles, and the light is projected by the tube C and the lens F. The wire is stretched between the points C, and with the flow of the current in the direction indicated by the arrows, a deflection is obtained shown by the horizontal arrow "a," which is at right angles to the magnetic field NS. Even a minute movement by the wire is greatly magnified by the telescope. For projecting on a screen, the eyepiece is removed and by sending a powerful light ray thru C, we see the image of the middle part of the wire on the screen. The screen is placed one meter away from the wire, inasmuch as the deflection will vary with the distance. The instrument may be calibrated to note the amount of current necessary to produce a deflection of one millimeter division at one meter distance. This is a standard of calibrating all types of galvanometers.

It was found from actual experiments in determining the sensitiveness, that the string will be displaced one millimeter at currents as small as 10⁻⁸ ampere (1,000,000,000,000) or one-thousandth of an ampere. Several millimeters or even centimeters of deflection can be obtained with the aid of the optical instrument and with currents of values of 30 to 40 micro-amperes, (one micro-ampere = one-millionth ampere). It is thus seen that the instrument is extremely sensitive.

Some of the most valuable features of this instrument are:—its quick action, its dead beat, and its quick period of swing, this being due to the almost negligible weight of the moving part, its moment of inertia being extremely small. Also it possesses practically no self-induction or capacity. It was found that with a wire of standard length and thickness which is one-thousandth of an inch thick, that the period of the wire is 1 second. This is small enough for practically all speeds of code reception used by commercial radio companies.

To electrical the period of the string by an actual measurement is a difficult problem. However, the following may be found of interest, especially to the more advanced student of electricity. If a short current be sent thru the string by means of suddenly tapping a key connected with the string, it is given a jerk and is displaced thru a distance d (at the center). It then swings back to zero and then past the zero point, due to the slight moment of inertia which it possesses. Calling this distance X, the point is thus d-X from it, where d-X is less than d. If a damped oscillation is sent thru the wire, the string does not actually come to rest for a definite time. During this time there may be a complete vibration from which the natural period t/n can be ascertained. If the string be made to cast a shadow over an illuminated slit thru which the light passes when it is displaced, and this light falls on a rapidly traveling band of a highly sensitive photographic film, and a top be then given with a key or switch, a record of the movement of the string is obtained. If the rate at which the film travels is known, it is a simple matter to calculate the period of the string of the galvanometer.

The string has a shorter period if its length be shortened or its tension increased, and the damping of the oscillation can be effectually increased if a twist be given to one end of it.

It is thus seen from the above discussion that the character of the string, its material and manner of suspension has a great deal to do with the sensitiveness of the instrument. Also the intensity of the magnetic field wherein it is placed has considerable to do with its sensitiveness. The table below gives an excellent idea of the period of the string, its resistances, etc.

This will suffice for the discussion on its operation. Let us now turn our attention to the more important topic for the constructor, namely giving the reader complete dimensional details on the construction of a sensitive Einthoven galvanometer, which the author built several years ago. Fig. 4 is a photograph of the completed instrument. This galvanometer was used for experimental work in radio-communication and its sensitiveness was found to be three-hundredths of a milliampere for one millimeter deflection at one meter distance from the screen. This was found to be sensitive enough for practically all kinds of work where small currents were dealt with.

Detailed assembly of the galvanometer is given in Fig. 4 A. The base 1, is made from three-quarter inch hard wood stock, and the drilling layout is given in Fig. 5. All holes are to be drilled with a No. 18 twist drill. The magnetic field is derived from two electro-magnets 2, 2, and their construction is shown in Fig. 6. The core is a piece of wrought iron one-half inch in diameter. The ends are machined down to four and one-quarter inches. Two fiber bobbin checks are placed on each end. Two holes are made in the lower end with a

A Graph for Solving Wave Length Frequency Inductance and Capacity

By E. M. T. (RADIO ENGINEER)

The scale starts at the bottom with one centimeter of ordinates. The main division is for 10 centimeters, and from the starting point the following main division is for 100 centimeters. As the scale extends to 100 centimeters or 10 times the first main division, which is about one-inch long, it may be quite readily estimated that 10° diagonal of the upper right-hand rectangle. If the work is done instantly, straight lines in any direction will intersect nearly the corners of the main rectangles.

Now note this property of the double rectangular logarithmic scale used in this graph. If a straight diagonal line is drawn thru the corners of the main divisions from left to right in the downward direction, the product of the values of the vertical and horizontal lines at the intersections is constant. This may be noted by inspection. It should be noted for any other parallel line and the logarithmic subdivisions.

Now, for a constant resonant frequency, the product of the values of capacity and inductance must be constant. Therefore for any constant value of this product the frequency is constant and will give the logarithmic relation to the scales, which is much simpler than a curved line relation.

The graph is so simple that it may be easily expanded to any extent in any direction or any given section may be enlarged to any extent if greater range or greater emphasis is desired. If a straight line is drawn thru the corners of the main divisions from left to right in the downward direction, the product of the values of the vertical and horizontal lines at the intersections is constant. This may be noted by inspection. It should be noted for any other parallel line and the logarithmic subdivisions.

For instance a constant microfarad, the product of the values of capacity and inductance must be constant. Therefore for any constant value of this product the frequency is constant and will give the logarithmic relation to the scales, which is much simpler than a curved line relation.

CLOCK-SPRING HEAD BAND.
In the ordinary watch-case receiver the loop for hanging on the hook is placed as in Fig. 1. An idea occurred to me thru an accident which happened to the receiver I was examining. I dropped it, breaking the loop off. When I picked it up I noticed the placement of the loop and an idea came to me. I thought of getting a clock spring 3/16-inch wide and bending it and placing it in as theloop had been and so forming a head band. I procured an old clock spring from a discarded clock and bent it to fit my head. I then bent it as in Fig. 1 to fit the hole in the receiver. I put the spring into place and put the piece of rubber back, and heating a large nail I ran it over the cracks left between the piece and the receiver. I then emerced the surface until it was smooth. In this way a fair head-band can be made for and by the amateur.

Bending the free end of the spring out as at Fig. 2 will avoid scratching the face.

A "VEST POCKET" RADIO SET.
I give herewith a sketch and details of a small pocket receiving set. I know that many of your readers would like to make one. I have tried mine out on the big antenna at NAA, where I am an operator, and found that I can get quite a range of wave-lengths on it. The secondary is wound with No. 32; the primary with No. 30, silk-covered magnet wire, 20 turns to a contact; 10 contacts to both secondary and primary. A flat condenser is shunted across the 'phone terminals; it is made of thin tin-foil, about sixteen square inches, wrapt in waxed paper. The detector is galena. All parts are nickel plated and mounted on hard rubber. The coupling is flat. QST from NAA could be heard faintly. Waves from 300 to 1200 could be heard good.

ELECTRICAL EXPERIMENTER

UNIQUE SCHEME FOR LEARNING THE CODE.
The writer some time ago decided to learn the code, and it occurred to him that as he had an "I. C. S." language phonograph, it might be used to advantage in this connection. At first a buzzer and telegraph key were rigged up, the recorder and a blank record was placed on the machine, and a few notes were recorded. When reproduced, the results were not entirely satisfactory as the sounds were rather weak and ragged. Then the following scheme was tried out and the results were good clear tones somewhat similar to a 500 cycle station.

A telephone of five dry cells, the primary of a local battery induction coil and a telephone transmitter were connected in series. The 75 ohm bi-polar receivers were connected in multiple, across the secondary of the induction coil. One of these receivers was supported so as to face the transmitter and be tight up against the mouth-piece. This produced the ordinary well-known "howler" effect, whenever the telegraph key was closed.

One of my indulgent commercial telegraph operator friends have become interested, volunteered to make me some records. The phonograph was adjusted to a speed of about 100 R. P. M., a blank record put on and the second receiver held in front of the speaking tube of the phonograph, while my friend tapped off the continental code, running thru the alphabet at the rate of about 8 to 10 words per minute and repeating each letter four times. Next some reading matter was recorded on another record at a slow rate of speed. When the reproducer horn were placed on the machine and the records run off, they turned out excellent and could be read anywhere in the room.

A few records made in this manner act as a constant guide to the beginner and enable him to rapidly learn what good signals should be. Assuming of course, that the records were made by a good operator.

HINTS ON SECONDARY TAP LEADS.
In making taps from the secondary of a loose coupler or on a primary switch, many readers undoubtedly have a great deal of trouble. A little wrinkle which I found, eliminates all the bother caused by these taps. First the taps should be taken thru the tube in the manner shown in the illustration.

After the wire is past thru the tube, apply a small speck of sealing wax, a little away from the hole thru which the tap is brought. A little more wax is placed on the wire after it has been straightened, near the ends, which will contain the switch. By this method there are no loose wires in the secondary, and therefore none liable to cross or get tangled with the support rods.

Contributed by ALBERT W. WILSON.

A CLEVER WAY IN WHICH TO SECURE AND BRING OUT THE TAP LEADS ON THE INSIDE OF A LOOSE COUPLER SECONDARIES. THEY ARE FASTENED IN PLACE WITH SEALING WAX.

A MINIATURE RADIO BUZZER.
The base of the buzzer should be made of some tough wood or fiber, the dimensions being left mostly to the maker. The single electro-magnets consist of a soft iron rivet or brand similar to boiler rivets, but much smaller, the one needed here being about 3/16-inch in diameter and 1 inch in length. A hole is bored in the base and the rivet forced thru with the head set flush with the under side, as shown. Wind the projecting end of the core with at least four layers of No. 30 B. & S. silk-covered wire. Now, connect the ends of the coil to two consecutive binding posts, three having been erected as near the edge of the base as possible.

The armature or vibrator is made of a corset spring or something similar. The corset spring must be heated to a cherry red and then bent into the desired shape. Bend the spring as shown, so that it will stay about 3/16-inch above the magnet when mounted as shown. A hole is then punched in the spring and a short piece of silver wire riveted into it. This is one contact point. A wire is now led from the armature to the remaining binding post.

The current is conveyed to the armature thru a soft copper wire bent double and hammered together at the contact. It has a piece of silver wire or platinum soldered to it at the contact point. This wire is connected to the middle binding post and then bent over so as to barely touch the contact on the armature.

This buzzer could no doubt be reduced in size until the hand could be covered over it; yet it does its work, as well as one twice or three times as large, and it can be used to an advantage in a portable wireless set or for learning the code, etc. etc.

A Simple Hand Milling Machine

By THOMAS REED

Honest, I'm sorry about that "Arabian alarm-clock," Boggs. I know you were just beginning to feel, whenever you saw my name attached to an article, that you were assured of a sober, dependable ex-
cient except for the fact that in operation the machine is held firmly in the vise, C, which gives all the stability required.

The soul of the machine is the index-
plate, D. This is a disc of thin metal, per-
forated with rings of holes, to which the
work is attached (see Fig. 2) and as the
plate and shift turn, they carry with
them the work G, held on by the nut
H. Long pieces of work can be steadied
by the back-center S.

While the work is being operated on—say while the ratchet-
tooth J is being filed out—the index-plate is held in a fixed posi-
tion by the spring-
lever K; a peg L, on the
end of which enters one of the holes in the plate. The
leever, with its peg, is
placed in line with any
of the circles of holes by loosening the wing-nut M, on the
bolt of which the
lever K is pivoted.

The ratchet-tooth J correctly, is sure to "come out right."

The holes in the index plate should be spaced off and drilled as accurately as possible, but errors tend to eliminate themselves, from the fact that the diameter of the index-plate is so much greater than that of the work. If you drill the plate anything like near enough to satisfy you, you will be surprised at the apparently perfect regularity of the work.

It is best to make the index plate from 1/16 inch stock, but thin sheet iron will do. If we must (which is my delight) draw on our household resources, I should think the bot-
tom of a tomato-can, carefully unsoldered by rotating over a gas-flame, would make an excellent plate. And don't forget the invaluable pie tin.

The guides, Q, Q, which hold the file P, should of course, be made out of steel, and hardened. The pivots R, R, are eccentric with the shaft E, so that the file may approach the work at different angles.

Fig. 3 shows a hack-saw guide. The disc turns eccentrically at T, forming a variable bottom-stop for the saw.

Fig. 4 shows two forms of punch-guide, where pegs are desired to be set at regular intervals, as in making rotary spark-gaps. After marking the work, the punch U can be withdrawn from the sleeve W, and the hole drilled with a hand-drill. This peg-

Not Only Is It An Extremely Serviceable Device, But It Gives the Fundamental Ideas of the Larger Milling Machines. This Device, Altho Quite Simple, Is Capable of a Surprisingly Large Variety of Work.
that even the wild requirements of a “Bug” may find essential to his happiness!

Oh,—as the numbers of the holes in the index-plate; a ring of 60 holes gives you the equal divisions: 2, 3, 4, 5, 6, 10, 12, 15, 20 and 30. Another ring of 56 holes would give you 7, 8, 14, and 28. This covers most of the desirable low numbers, and shows how easily you can figure for yourselves any other factors you need.

THE PRODUCTION OF RADIUM FROM U.S. CARNOTTE ORES.

As one of the results of an agreement between the National Radium Institute and the Bureau of Mines, Department of the Interior, to develop a more efficient process for the manufacture of radium out of the carnotite ores of Colorado and Utah, the Bureau of Mines now has as its share more than $180,000 worth of radium for use in the sciences. This was procured for an expenditure of less than $8,000. In addition, under the agreement, the bureau has turned over to the National Radium Institute about 6½ grams of radium, and has given the country a method of producing pure radium compound from the ore for one-third the current price of radium.

When the Bureau of Mines began this work in 1912, it found that the precious carnotite ore, constituting the largest known supply of radium ore in the world, was going to Europe, mainly to Germany, where it was being turned into radium and sold back to the United States at fabulous prices.

ELECTRICAL

A MERCURY FIRE ALARM.

Here is a drawing and a description of an automatic fire alarm which I believe will be of interest to your readers.

The device makes use of the expansion of mercury when heated. It can be quickly adjusted and requires no reset setting. The fire detecting mechanism is clearly shown in figure 5.

It consists of a glass (or brass) tube about 2” long and having a bore of ½” or a trifle more. The lower electrode has a short piece of copper wire soldered to it 4” long. The rod is fitted into the tube as shown and then the end of the tube is filled with the sealing wax. The rod should not fit too tight or its expansion will break the tube.

A small rubber cork that fits the tube tightly has a needle run thru it to form the upper electrode. A short length of wire should be soldered to this needle as shown in the drawing.

The tube is fastened to the base, measuring ½” by 3” by means of a brass strip and two small screws. Binding posts are mounted on the same base, and the wires are connected to them.

A few drops of mercury are put in the tube and the rubber cork and the needle inserted as shown in figure. By regulating the distance between the needle and the surface of the mercury, the temperature at which the alarm is given can be regulated.

A good method of adjusting this apparatus is to connect a bell and battery to the terminals. Place the instrument and the thermometer in an oven bath and adjust the needle so the bell just rings when the thermometer registers 110 degrees Fahrenheit.

With such a system an annunciator may be used to indicate from where the alarm came. This device has been used by the writer for the past two years with success.

KEEP YOUR STRAW HAT ON TO AVOID SHOCKS.

An engineer suggests in a recent issue of Safety First the wearing of straw hats with stiff brims for those employed around electrical stations. It seems that the straw hat is far superior to a felt hat from the safety standpoint; for should the head come accidentally in contact with live wires, the rim of the hat or the crown prevents injury, and gives the necessary warning. The same holds good when working around steam pipes. In a recent accident, where a man unconsciously came in contact with a 12,000-volt line, he would have been protected had he worn a straw instead of a felt hat.

The singing of telegraph wires is sometimes regarded as a weather prognostic, though opinions differ as to the kind of weather it foretells. There has been much discussion as to the cause of this sound. Probably it is simply the Aeolian harp effect, and its occurrence depends chiefly upon the direction of the wind in relation to the direction in which the wires run. Variations in the pitch of the sound depend upon changes in the tension of the wires with varying temperature. Electricity, contrary to popular belief, has absolutely nothing to do with the singing.

A SIMPLE BUT POWERFUL HAND-FED ARC-LIGHT.

The arc-light shown can be made from odds and ends at a very small cost and can be used for wide variety of purposes. A piece of wood for the base, some strips of brass, a few battery binding posts, screws, drop cord and plug, and two battery carbons in a fruit jar, with a small piece of fiber insulation are all the articles needed to construct the arc. The fruit-jar resistance is one novel feature. Two ordinary battery carbons are held at a fixed distance from each other by two strips of fiber, the bottoms being about ¼ of an inch and the tops about ½ of an inch apart. Rubber insulation cut from an old tire may be used for handles at the end of the strips holding the arc carbons. By moving these handles the arc may be raised or lowered or fed together. After the wiring is completed fill jar ¾ full of water, add a little salt and connect the plug with a regular 110 volt house light socket. This will make it necessary to put heavier fuses in the fuse block. This arc will melt any substance placed between the carbons, as it will give from 3/4 to 1 ½ flame. If a housing is placed over the base, as shown in dotted lines, and a reflector used with a common reading glass in the sleeve, the arc will cast a powerful beam for a distance as much as 2 or 3 miles.

The Manipulation of Glass Tubing in the Experimental Laboratory

By Prof. HERBERT E. METCALF

PART I.

In the experimental laboratory there is always a demand for small pieces of apparatus which are made out of glass, and yet are usually too high in price to be purchased on the market. Again, when the apparatus may look simple to make, most all experimenters, after breaking enough glass to nearly pay for the finished article, give up the job in disgust and worry along without the apparatus. But if they had a little knowledge of simple glass-blowing they would save many dollars, and enrich their laboratories with many pieces of apparatus not otherwise obtainable.

In the first place the manufacture of small articles out of glass tubing is not hard; in fact, with the proper glass, the proper heating agents, and a little patience, nearly every commercial article made from glass may be functionally duplicated. You will notice that I have said "functionally" because often it is not possible nor at all necessary to duplicate the article. Its function is the standard, and if the home-made machine will do as good work, that is all that is necessary.

THE KING OF GLASS TUBING TO USE.

To begin with, the glass tubing MUST BE fresh. The experimenter cannot expect good results from glass tubing which has been lying around his laboratory since the year one. That is why such poor success is attendant upon many efforts in this direction. He will have to go directly to the largest supply house in his city for the best, softest glass tubing suitable for bending. To get hard glass such as boiler glass tubing will spell failure immediately. If there is no supply house close at hand then write an order to the nearest large supply house, in all cases specifying explicitly that the tubing is to be fresh soft glass to be used in the flame. Given the proper tubing be obtained from the local hardware store, as it will probably be many years old. All this is extremely important, for the entire success of all future operations will depend upon the quality of the glass. Glass tubing becomes brittle with age, and a piece of tubing much over a year old is very apt to crack no matter how carefully heat is applied.

EQUIPMENT NEEDED FOR THE MANIPULATION OF GLASS TUBING.

For simple bends in tubing an ordinary Bunsen burner is needed, provided it be equipped with good fuel. In fact, all work which does not need fusion may be done with a burner of this kind.

For more complicated work which does require the fusion of glass, an air blast must be added to the flame in order to obtain the high degree of heat necessary for the proper joining of the glass. This may be simply a small tube held in the mouth. By blowing air thru a yellow flame a fairly good blast burner may be had, but it is not very satisfactory because a steady blow cannot be maintained, nor can the size of the flame be suitably regulated. The most practical thing to do is to buy, new or second-hand, an adjustable flame blast lamp. The air supply may be obtained in several ways; from a pump, foot blower, or a water jet air pump, of the type described elsewhere in this issue.

An asbestos mat such as used on the table may be obtained at any hardware store, and is needed to lay the hot glass on while it is cooling. Hot glass must NEVER be laid on metal to cool, and as it will burn other materials this mat is indispensable.

The blast lamp must be placed on the experimenter's table with the flame directed away from him and with the mat on his right, so that he will be able to use both hands on the glass tubing, and then place the finished product on the mat to cool. Fingers are better that pieces of any kind and a pair of kid gloves will save the hands from many a sharp burn. A supply of small corks to fit all sizes of tubing may be obtained from a supply house or may be whittled out of drugstore corks. These are very important in nearly all operations and may be used over and over again. Several feet of rubber tubing of various sizes, a generous stick of sealing wax, and a sharp three-cornered file fits us out.

Now that we have assembled before us all our materials; the glass tubing of the diameter required, the burner in its proper position connected to its gas and air supply, the asbestos mat and the corks where they may easily be gotten at; we will take up the file and proceed to the first operation, cutting the tubing to its proper length. The following operations should be very carefully read over before being performed, even going so far as to rehearse before hand, because there is nothing so discouraging as to sneak a look at the printed directions in the middle of an operation, and then returning to work only to find that the glass had cooled off while we were reading. It should have been kept hot, and when the flame played on it again it cracked.

CUTTING GLASS TUBING.

Glass tubing up to one-half inch in diameter may be cut with a sharp three-cornered file. Place the tubing in front of you and make a single deep cut in the tube at the proper length, and then break it by grasping the tube in both hands, one on each side of the cut, with the thumbs meeting directly opposite the cut, see Fig. 1. Then push outwards with the thumbs, and a square clean break will result. In case one end is short, wrap your handkerchief (Continued on page 340)
TRICK "SHOCKING BATTERY."  
A "shocking battery" represents a novel departure from the ordinary shocking coil, and is nothing more or less than just such a coil, enclosed in a case so that it closely resembles an ordinary dry cell. How to make it: First turn down a wooden block to 2 1/4" diameter and 1/4" thick. Leave a small extension 3/8" thick and 1/8" diameter on one side, to resemble the carbon rod of a dry cell. Drill holes for the binding posts and cut four small slots at the edge 90° apart for the battery supports. When finished paint the block black and place in the binding posts. It should now closely resemble the top of a dry cell. Cut two blocks to 2 1/4" diameter and 1/4" thick. Drill a hole large enough to accommodate the coil to be used in the battery. Do not drill it directly in the center, but off to one side so as to give ample room for the vibrator. The coil to be used may be an old shocking or "medical" coil, a telephone induction coil or one may be made for this purpose. Another block is now turned down to 2 3/4" diameter and 1/4" thick and properly notched for the supports. On this block is mounted a small single-pole, single-throw side-action switch and two binding posts for the primary. The complete battery is now assembled, connections being made and parts fastened together by the battery supports which are wooden strips 6" long and fit into the notches provided for them. The battery is now rapt up in some card board or heavy paper. It would be well to fill in the space around the coil with some insulating compound to increase the insulation. The whole is now placed in a sheet metal container fastened to the same with screws which is in turn placed in an old battery carton that has the bottom knocked out. A concealed flexible lead is now connected to the primary binding posts and the "battery" is ready for action. It may be operated by a flash-light battery concealed in the case with the coil. Initiate your electrical friends by having this "battery" on the table beside several other regular cells. They will see that you will bet they cannot connect up the cells properly, in series, parallel, etc. Let 'em have it, when they get to making the connections.

**HOW TO "STEEL-PLATE" PARTS.**

"How automobile parts and all sorts of machinery are steel-plated" should be an interesting topic to the readers of the "E.E."

Purchase some Potassium Ferrocyanide in a drug store or other chemical house. Great care must be taken in handling this chemical compound as it is one of the most deadly poisons. To show its fatal effects, one can perform the following experiment. Drop a small piece of this compound into an old enamel coffee cup. Immediately its head begins to droop and then the cat stretches itself out and dies.

Dissolve some of this Potassium Ferrocyanide in water and put it in the iron to be steel-plated. This should be left in the solution for about 48 hours. After the iron is taken out it is heated in a furnace or even over a stove for a short while. Then a steel coating is permeated into the iron. From the chemical standpoint the action is a very easy matter to explain: After the iron is taken out of the Ferrocyanide it has a practically pure coating of iron. Then when it is placed in a furnace, the carbon escaping from the coal, unites with the pure iron coating to form steel.

This is used a great deal in auto parts manufacturing.

**HOW TO MAKE A SMALL COMMUTATOR.**

Procure a piece of brass tubing the diameter and length you wish your commutator. Push pipe used by plumbers is very good for this purpose. It comes in sizes from 3/4" inside diameter up to 2" and is seamless and uniform. Square up the ends in a lathe or if one is handy, on, if not, a file and try square will serve. Then set the dividers and scratch lines around the tube from 3/16" to 1/4" depending upon the diameter. Space off the tube into as many segments as there are slots in the armature, and, with a scriber mark the sections where they are to be divided. Use a fine hack saw, or a piece of clock spring held on edge in the vise and hacked with a sharp edge file. This makes an ideal saw for the purpose. Saw along the dividing lines from each end until you reach the lines A-A, as in Fig. 1. After all the slots are sawed take a saw file and file down each until the tube has

LESSON VI.

Thread Cutting and Metal Turning

Considering that the novice has become thoroughly familiar with the rudiments of plain "thread cutting" as given in the last lesson, and taking also into consideration that the amateur has become a junior master of handling the shift gear problem, the author will now further discuss the subject.

As the student will remember from the preceding lesson the subject of cutting "V" threads was under discussion and now a second type of thread will be taken up and this is the square thread. A very good illustration showing how a square thread looks is given in the first illustration. For cutting such a thread a different type of cutting tool will be required, and in Fig. 2, we see the type of tool necessary for this kind of work. This tool is very similar to a parting tool, only that the rake must be provided for in the portion that enters the work to prevent side rubbing, thus destroying the value of an accurate thread. The tool holder as shown simplifies to a great extent the cutting of a square thread. The tool itself is filed up out of a small round piece of tool steel, which is then fixed to the tool post holder by means of a set screw. The tool steel being circular in section, can be turned around in the holder before the set screw is tightened, so as to give any desired degree of rake.

The width of cutting edge of the tool must be equal to half the pitch of the thread. This is evident from the first illustration where "I" shows the pitch of the thread, which is equal to the thickness of a thread and space. The exact width of the cutting tool should be equal to the space R, or exactly equal to one-half of P. For cutting a double or triple thread, the case becomes different as will be seen from the third illustration, which in this case represents a double thread. Here the pitch P is equal to the thickness of two threads and two spaces, so that the width of the cutting tool must be exactly equal to one-quarter of the pitch P. In the fourth drawing is shown a double thread screw with only the first thread cut. When the second groove is cut in the center of the intervening portions of the work, it results in a double thread.

A very neat way of finishing off a square thread is to drill a small hole into the work at the end of the thread for the tool to run into, as is indicated in Fig. 1. The diameter of the hole should be slightly larger than the thickness of the tool, and the depth a little greater than the depth of the thread. The lathe must be stopped just before the tool reaches the hole, and pulled around by hand for the last turn or so. As soon as the tool finishes its cut, it is withdrawn and run back again in readiness for taking a fresh cut.

In Fig. 5, the student will note the various types of threads that can be cut with the aid of a lathe. It gives a splendid idea as to the kind of work the amateur can carry out with this machine if he once becomes skilled in operating it, and experience is the best teacher.

The procedure in cutting square threads is identical as for those for cutting "V" threads, with the exception that a different shape of cutting tool is used. It is impossible to cut very fine pitch square threads as the pitch of this form of thread is dependent upon the width of each tooth, which is naturally wide. Square threads are extensively used in machinery where there is a great stress, and where a large motion is desired with a minimum angular movement of the shaft containing the square thread.

The experimental machinist will find of great help a newly devised rotating thread cutting tool, applicable only for cutting "V" threads, and this tool is shown in Fig. 6. Its application to the work is shown in Fig. 7. The tool consists, as will be seen, of a disk of steel having ten distinct teeth on its rim. These teeth are graded for cutting the thread in distinct operations of the tool. The cutter is mounted on a hand slide rest, which is bolted to the ordinary lathe carriage, and the tool is adjusted to each cut by the hand lever as shown in Fig. 7. When fine work such as for taps, etc., is required, the pawl is thrown back out of action, the micrometer adjustment used, and another trip taken across the thread. Advancing the lever one hole in
the micrometer adjustment, brings the cutting point a fraction of a thousandth of an inch forward. Successive trips with advance of lever will give the finest finish possible to a thread.

The heel of the tooth in action rests upon a stop, so that it can be ground until but an eighth of an inch in thickness, and still retain the full strength and power to do the work. When once set, neither tool nor cross-slide adjustment needs to be changed in cutting the screw or any number of screws in exact duplication. This type of tool requires very little grinding, as the point of the tool is reserved and only used in the finishing or last cut.

METAL TURNING

The author strongly advises the novice to become a thoroo master in the making of threads on his lathe as after all, experience will teach him more than a thousand articles which he will read on the subject. It was the intended purpose of the last two articles to lead the student of mechanics to obtain a fundamental understanding and allow himself to grasp it thoroly by actual practise. We will now turn our attention to the next important subject, namely, "Metal Turning."

In discussing this topic, let us take a sample at random of round stock of any predetermined diameter, and let the problem of the job be to turn down one-half of the stock to a certain diameter, also having its both ends turned to a certain prescribed length, and one end to have a hole threaded with a certain thread. The first thing to be done with the job is to cut the rod of stock one-quarter to three-eighths of an inch longer than the finished length required by the job, so as to provide sufficient material with which to "face off" the ends. Blueprints used for machining operations are marked with a lower case "f" or the word "finish" on all surfaces which are to be machined or accurately finished to size.

Having done this, the next step is to turn down the ends, and care should be exercised to see that the metal taken from each end should not exceed the amount necessary to make the rod of the exact required length. The rod is placed and firmly secured in a scroll or independent jaw chuck on the live spindle, and by means of a left or right hand side-cutting knife, depending upon the position of the chuck, the end is turned down. The amateur will find it worth while to turn to lesson 3, Figs. 7, 8, and 9, to give him proper information relative to these cutting tools. When one side is finished, the work is removed from the chuck and the other side is turned down. In the lathe cut proper precaution should be taken not to take off too much material, as it will reduce the predetermined length. The photograph Fig. 9, clearly illustrates how the piece of work is held in the chuck, and how its end is being squared.

The next step is to provide centers on each end, so as to secure the work between the live and dead centers of the lathe. This is to be used only when an accurate job is required, and especially when the work is very long. In order to do this, a center drill will be necessary, and the work should be secured to the chuck of the live spindle. The center drill is held in a drill chuck secured to the tail-stock spindle. Illustration Fig. 10, shows clearly just how this is done.

Care should be taken to see that the drill is not fed too quickly or else the drill point may break.

The third step is to place the work between the centers of the lathe, and to secure it to the face plate by means of a dog. Fig. 7 of lesson 3, shows how this is accomplished. Before starting to turn the rod, carefully oil the dead center as it will heat considerably when the end of the work revolves upon it, and thus destroy the hardness of the center. To reduce one-half of the stock to the predetermined diameter, it will be necessary to utilize a diamond-point tool in the slide rest of the lathe, and with the aid of this tool proceed to take the initial cut and run the tool approximately to the center line of the work. Then bring back the tool to the original position, and repeat taking off a certain amount of metal until the (Continued on page 339)

Fig. 10. Illustrating How the End of a Shaft is Exactly and Quickly Centered By Means of a "Centering Drill" Held in a Hand-Chuck Mounted in the Tail-Stock Spindle of the Lathe. If no Centering Drill is Available, an Ordinary Twist Drill, Ground to the Proper Angle, is Used in Many Shops.

Twenty-Eighth Lesson

WATER, HYDROGEN PEROXIDE AND OZONE.

The chlorides, and especially the chloride of sodium, is universally present in natural waters, being derived both from the dried salt spray in the atmosphere and from the soil. The amount present in perfectly pure water varies enormously, depending largely upon the distance of the locality from the ocean, from saline springs, from beds of rock-salt, and also, in general, upon the nature of the soil. Besides this, common salt is always present in considerable quantities, not only in animal excreta of all sorts, but also in kitchen refuse, etc., which forms a large part of ordinary sewage.

It is easy to determine, with great accuracy, the quantity of salt present in water or in other neutral solutions, by using a standard solution of silver nitrate, with a few drops of potassium chromate to act as an indicator. The red cromat of silver produced by the latter is decomposed into silver chloride as long as any chlorides remain in solution. But directly the latter have been precipitated, the silver cromat gives a red or orange color to the solution. Thus as long as there are soluble chlorides present, 
\[ AgNO_3 + NaCl = AgCl + NaNO_3 \]

but when they have all precipitated,
\[ 2AgNO_3 + K_2CrO_7 = Ag_2CrO_4 + 2KNO_3 \]

The standard solution, of the strength used and described, contains 1 gram of silver nitrat in 401 cc. of water.

Experiment No. 142.

CHLORIDES (Quantitative Determination).

Measure 50 cc. of Croton water into a beaker, and add one drop of potassium chromat. Now run very carefully, from a burette, (See Fig 128) the standard Silver Nitrat solution, stirring constantly with a rod. Notice how the red precipitat of silver chromat which is formed by each drop of the silver nitrat solution, dissolves when it is mixed in with the yellow liquid, and is converted into a white or yellowish cloud of silver chlorid.

When the red precipitat dissolves slowly and with difficulty, add the silver nitrat solution only a drop at a time, stirring well after each addition, until the color of the mixture just changes from yellow to orange or orange red. Then stop, read the burette, and the number of cc. of standard solution used (for this quantity, 50 cc. of water) will equal the number of grains of sodium chlorid in one gallon of water. Repeat this test with well-water.

WATER FOR MANUFACTURING PURPOSES.

Experiment No. 143

QUALITATIVE TESTS.

Half fill three test-tubes with well-water, and test them as follows:

1. For Chlorides—Add one or two drops of dilute nitric acid and one or two drops of silver nitrat. Result—precipitat of silver chlorid.

2. For Sulfates—Add one or two drops of dilute hydrocholoric acid and one or two drops of barium chlorid. Result—precipitat of barium sulfate.

3. For Lime—Add one or two drops of ammonium hydroxid and ammonium chlorid then add a little ammonium oxalat. Result—precipitat of calcium oxalat.

Repeat these tests with Croton water, and notice that in this the precipitates are almost imperceptible, altho quite distinct in the well-water.

Quantitative Determination of Hardness.

Place in a stoppered bottle 100 cc. of Croton water and add, from a burette, some "Standard Soap Solution," shaking well after each addition. Stop when a permanent lather is formed, and when, on shaking, it sounds and feels soft.

Each cc. of soap solution used is equal to a quarter of a grain of calcium carbonate in one gallon of water.

Repeat this test with 50 cc. of the well-water. Notice the formation of a "false lather" of lime or magnesium soap before the true soft lather. With this quantity of water, each cc. of soap solution corresponds to half a grain of calcium carbonate per gallon.

MINERAL WATERS.

Experiment No. 144

Test the sample of mineral water as follows:

1. Bicarbonates of Sodium, Calcium and Magnesium.

(a) Notice that the water is alkaline to test paper, after it has been boiled for a minute or two to expel the carbon dioxid.

(Continued on page 341)
**HOW I MADE A "RADIUMGRAF."**

I am sending you a picture, or rather "radiumgraf," in the hope that it may prove of some interest to fellow experimenters.

The picture was made with a spinthariscope. It was made thru two thicknesses of black paper. The word "Radium" was cut out of heavy lead foil and pasted on the paper so as to read backwards. An ordinary photographic plate was placed, emulsion side up, under the paper. Then the lens of the spinthariscope was removed and the part containing the radium salt was placed over the first letter. It should be left on each letter for at least forty-eight hours to get good results.

As will be seen the lead foil stops the rays, while the black paper does not. In this respect they are similar to X-rays.—Contributed by VERNON G. CLEMENTS.

**A MINIATURE "BOOK" LIGHT.**

Here is a miniature light for use on books when traveling, etc. A simple book light can be made by bending a strip of brass ⅜-inch thick and 1 inch wide, as shown in diagram. Bore a hole thru it large enough to receive the lamp, which should fit snugly. Attach two strips of thin spring brass ⅜-inch wide to the other end of the first piece of brass to act as spring, which can be slipped over the cover of the book. The wire connections are shown in the illustration.—Contributed by MERREL HALLOWELL.

**THE COLLAR BUTTON AN ELECTRIC NOTION.**

Fig. 1 shows a spark gap made of a base and two binding posts of the type shown. Simply pass the wires from the secondary of a spark coil thru the posts. Next slip on the buttons, as illustrated, and adjust the distance.

In Figs. 2 and 3 the buttons are used as contact points (as for example, on a loose coupler). In Fig. 2 the board must be of a thickness equal to the length of the button less its head. Drill a hole large enough to pass the head of a button, which head is then flattened. Now place the wire in the hollow bottom of the button and solder it.

In Fig. 3 the board may be of a smaller thickness, as here the button is shortened by cutting off the bottom part (Fig. C). Drill a hole large enough to pass the neck of the button, but not the head. Flatten the head (if wanted) and the bottom. Then insert the wire and solder.

Contributed by B. DOPPEKE.

**FOR PLUVIUS’ SAKE—RAIN ALARMS AGAIN.**

I give herewith a diagram of a rain alarm which I think original. Its principle lies in the fact that, when a board is wet on one side, it warps. Referring to diagram, rain falls on board A, causing it to warp, closing contacts and ringing bell in circuit. Board A has one end free to permit its warping. The thumbscrew is turned until correct distance is obtained.—Contributed by JACOB E. VOLLMER.

**A "BLOWN" FUSE ALARM.**

Sometime ago while doing some experimenting which involved the blowing of fuses, I could not readily tell without testing for current, whether my fuse was blown or not, so I hit upon this scheme.

I first procured a base of wood of the size measuring two inches larger than the rod R, which can be of brass or copper and should have three small holes bored in it. The one at the top holds the fuse wire F. The other end of the fuse wire is twisted around the post connected to the feeder. The center hole has a spring fastened so that its tension draws the rod up against posts C, closing the bell circuit and ringing the same. The rod is pivoted at the bottom hole. The feeder should be connected to

**GLASS-BLOWING LESSONS.**

In the October number there will appear the second paper of a series by Prof. Herbert Metcalf on the art of glass-blowing. These lessons explain every step with clear illustrations, so that you can learn the subject easily.—Contributed by BERNARD COHAN.
ELECTRO ZINC PLATING.

To zinc plate steel and other metallic objects mix the following: 3 parts of zinc sulfate with 4 ounces of water. Place this solution in an ordinary glass jar; next fasten a wire to the positive pole of a battery. Let this wire lay submerged in the solution. The wire which you have fastened to the negative pole of the battery should be arranged so that it will hold some metal object which is to be zinc plated. Drop the wire with object to be plated in the solution. Care must be taken not to let the two wires touch, for this will cause a short circuit of the battery. Using a 4-volt 60-ampere hour storage battery the action of the solution will be much quicker and the quicker will the zinc deposit itself on the object connected to the cathode.

Contributed by ED. H. RANSON.

THE MYSTERIOUS FIGURE NINE.

Has it ever occurred to you what strange feats may be performed with figures? Take the simple example of multiplying it by 2, and you get 18; and 1 and 8 make 9. Five 9's are 45 and 4 and 5 make nine again. Three 9's, and 1 and 9 make 9. Four 9's are 36, and 3 and 6 make 9. Take any row of figures you fancy, say 804, and if you reverse them and subtract 804—246—you have left 074, which added together makes 18, or twice 9. Take the 18 and 1 and 8 make 9 again. If you take five figures, say 78643, reverse them, 34657, which added together makes 27—that is, 2 and 7 make 9, or three 9's are 27. Thirty-seven is another number specially adapted for future guessing. Multiply by three, 37 becomes 111: and no matter what multiple of three you use the figures in the results will all be alike. Twelve times 37 is 444, 37x21 becomes 777, and so on.

HOW TO DRAW LINES WITH WRITING PEN.

Those who have tried to draw straight lines with their writing pen and take nine times out of ten have obtained an unsightly blot for their labors. Next and clean-cut lines may be drawn with the use of the following device. The thickness of the lines will depend on the kind of pen points used. The guide arm (A) may be constructed of brass, although steel is preferable in this case. The band (B) should be made of spring steel, a piece of spring of an old clock would be sufficiently elastic. What is required of the material would be that it should hold its form and not be easily bent.

Contributed by D. HUGHES.

WAX FOR BOTTLE SEALING.

Mix resin or cheap sealing wax with an equal amount of beeswax in a water-bath. Dip bottles in hot solution and lay on side until dry.

MISCELLANEOUS RECIPES AND FORMULAS.

TO SOLIDIFY ALCOHOL.—Heat 500 parts of denatured alcohol over a water bath to about 140 deg. F., and add 1 part of gumlac and 15 parts of dry Venetian soap (powdered).

BLUING (COLORING STEEL)—Small articles made of steel are very often blued. A very convenient method for the experimenter is to place the articles in an iron pan containing a quantity of clean dry sand over a fire. Move the pieces around constantly until the desired color is achieved, then remove and plunge into clean oil. It is very necessary that the metal be colored clean.

TO GIVE STEEL A BLUE-BLACK COLOR.—At times a blue-black color is preferable to a blue. Melt together in an iron dish 10 parts of saltpeter and 1 part black oxid of manganese, and heat until a pine shaving thrown on the surface will catch fire. DO NOT ALLOW IT TO BOIL. Wire each piece of work and suspend in the mixture. Be sure that each article is completely covered. Do not let them touch the container at any point. When the desired color is obtained, wash in hot water, dry in clean savadust and oil. TO COLOR BRASS A STEEL-BLUE.—Dissolve 3 drams antimony sulfid and 4 oz. calcined soda in 1½ pints of water.

To this add 5½ drams kermes. Filter and mix this solution with 5½ drams tartar, 11 drams sodium hyposulfite and 1½ pints of water. Polished sheet brass placed in the warm mixture will assume a steel-blue color.

TO GIVE APPEARANCE OF CASE-HARDENING.—To 20 parts water add 1 part nitric acid. Immerse the piece in the solution for about 30 seconds, remove and wash in clean warm water and oil.

TO REMOVE PAINT.—To remove paint without leaving any traces use ether on a piece of cheesecloth.

NO-GLARE HEADLIGHTS.—Paste a piece of ordinary blotting paper on the inside of the glass. A light so fixed is lawful and gives a good driving light.

LITMUS PAPER.—This paper is prepared by boiling litmus, and steeping the paper in the liquid; this paper turns red when touched by acids.

ROSEWOOD COLOR.—Boil in ½ gal. of water, 1 pound logwood chips and ½ pound red sandalwood. Apply to the wood, then go over it with a mixture of asphaltum and water.

ACID PROOF TABLE TOPS.—The following solutions render a table top impervious to all reaction of acids and alkalis.

Solution No. 1—Iron Sulfate............ 2 parts Copper Sulfate............ 2 Pot. Permanganate............ 4

A rivet is fitt to hold the guide arm and band together. Make a dent with a center punch above the rivet both in the arm and band to hold the former in place, as in the case of the extension or commonly called zigzag rule. No dimensions are given, although for ordinary pen-holder (A) could equal 9", B=½", C=1½", D=½", and XY=1¼". A desirable feature of the device is that the guide arm may be folded so that the pen may be dipped in the ink bottle as shown in Fig. 1, and in that position it can be used as a clip to hold it in the pocket also. The band may be constructed in any design suitable to the maker.

Contributed by W. H. W. (Chemist.)
Automatic Aircraft Steering Mechanism
(No. 1,264,906, issued to Gustave Nordstrom.)

When any key is depressed for either a short or a long period of time, the various operations necessary to complete the printing of a character and to return the typewriter to normal position will be automatically and progressively carried out. The movement of the type bars as the various keys are depressed is caused by electro-magnetic means, and to reduce sparking at the contacts whenever the electro-magnetic circuits are opened, the inventor provides a suitable condenser to absorb the stray energy created in the circuit by the self-induction of the magnet windings. A set of selective electro-magnets and an electro-magnetic power armature are utilized in operating this electric typewriter.

Multi-Unit Telephone Transmitter
(No. 1,264,507, issued to William Wallace Hanscom.)

A novel scheme for mounting the carbon cells is employed, and also in conjunction therewith a common cooling chamber is devised so that a continuous stream of cold water or other liquid can pass into the microphone chamber and circulate by the thin walls of the carbon cells, and thus carry off the heat produced in these cells when the microphone is carrying a heavy current. In the design shown, six carbon chambers are used.

Electric-Driven Refrigerator
(No. 1,263,633, issued to Heinrich Zeidry.)

This refrigerator embodies an electric motor at the top as indicated and there is also incorporated in the makeup of the machine a special form of compressor which is used in compressing the refrigerating medium, which may be methyl chloride, and which in the course of the refrigerating process is used over again. The refrigerating mechanism and receiving scheme for installation on ships, etc., the principal object of which is a motor-operated switch which alternately cuts in the radio transmitting and receiving set on the antenna. The speed of the switch can be regulated so that radio signals can be sent out and received in alternation during brief or sufficiently prolonged periods to be effective. The switch may be operated by electric motor.

A. C. Telegraph Sounder
(No. 1,265,585, issued to Arthur W. Headsinger.)

He provides a duplex core so arranged that there will be a mutual attraction between the two parts thereof, irrespective of the character of the current passing thru the solenoid or magnet. In this way, the inventor claims, the results are such that the residual magnetism in the two core members will at all times be great enough to hold the same in memory during the passage from a positive to a negative wave.

Current Amplifier
(No. 1,264,813, issued to August J. Klimek.)

An amplifying telephone relay is interposed between the signal stations, embracing two dynamo-electric current generators designed with suitable differential regulating coils as the diagram shows. Also the inventor provides relay members in these relays which do not have any collecting rings or commutators. The amplifying coils of the relay generators are arranged so as to be cut by lines of residual magnetic force at a rotating armature shank, which is induced in the latter thru the field coils of a generator. A current from a transmitter enters in the same direction thru the central coil as thru the main field coil and thus energizes the generator; but an amplified current from this generator enters thru a differential coil in the opposite direction to that in the main coil, thus nullifying its action.

Automatic Wireless Signal
(No. 1,265,615, issued to Gustaf Engellbrecht.)

An automatic wireless transmitting and receiving scheme for installation on ships, etc., the principal object of which is a motor-operated switch which alternately cuts in the radio transmitting and receiving set on the antenna. The speed of the switch can be regulated so that radio signals can be sent out and received in alternation during brief or sufficiently prolonged periods to be effective. The switch may be operated by electric motor.

REVOLVING ELECTRIC SIGNAL FOR WATER TANKS
(No. 1,268,175, issued to Frederick J. William Meyer.)

This novel patent covers specific means for mounting the revolving electric sign which is of the circular type and so arranged as to be suspended on tracks running around the tank. An electric motor works in a toothed rack mounted around the interior surface of the sign so that it will be carried around continuously as long as the motor is operated. Electric current for operating the lights on the revolving sign is carried to the lamps thru insulated rings and brushes.

A Lamp Socket Meter
(No. 1,264,922, issued to Edmund O. Schweitzer.)

This meter involves a small electrolytic cell which is appropriately connected into the lamp socket so that after a certain length of time the elements making up this cell will be decomposed by the passage of the current feeding the lamp, and which will cause the circuit of that lamp or apparatus to open. Before this lamp or apparatus can be again used, and more electric power consumed, the owner has to screw another meter unit into the socket, a supply of which he could have on hand at all times. Novel contacts are provided whereby the consumer is notified by a flickering of the light for a short time before the current is shut off by the electro-chemical decomposition of the meter elements, so that he will not be left in the dark.
"Amateur Electrical Laboratory" Contest

In this issue we publish some interesting facts with excellent photos, describing one Amateur Electrician's experimental laboratory. Now "Bugs"—we want to publish a snappy one like it each month. Here's our proposition: Why not write up your "Electrical Lab." in not more than 500 words. Dress it up with several good, clear photographs. If we think it good enough we will publish the article in display style and pay you well for it. The prize awarded to such articles will range from $5.00 to $10.00. And "Bugs"—don't forget to make your article interesting. Typewritten articles preferred. Address the Editor of this Department.

THIS MONTH'S $3.00 PRIZE WINNER—EUGENE MCGOWAN

Herewith are five photographs of my experimental laboratory. The lower right-hand photograph shows my chemical laboratory. The table upon which the apparatus stands was constructed from an old counter that was once used in a grocery store. In the center of the table there is a small basin that serves for washing test tubes, etc. There are also spigots for hot and cold water. Shelves were placed on the top to hold the chemical bottles as the picture shows. It may be of interest to the readers of the ELECTRICAL EXPERIMENTER to know that this table cost less than $4.00 to make, including the shelves, sink and the pipe fittings. There are about one hundred chemical reagents, including a few of the rarer elements like Radium, Bromid 40X and Uranium Metal. I also have balance scales, Kipp's apparatus for generating suffocated hydrogen, condensers, burettes, and other common laboratory glass ware.

The center and upper left-hand views show the Electrical "Lab." and most of this apparatus was constructed from data given in articles that have appeared in the "E. E." In the right-hand corner of one photo may be seen the vacuum pump, which was constructed according to the directions given in the "E. E." by Raymond F. Vase, November, 1917, issue. There are also spark coils, Tesla coils, a Hughes induction balance, galvanometer, storage batteries, static machine, Leyden jars, a small dynamo, several motors, Geissler tubes, a synchronous motor made according to the one described in the "E. E." April, 1918. Storage batteries are kept in a box under the table. The top right-hand photo illustrates my Tesla coil in actual operation. It stands two feet high and throws a discharge about one foot long and several inches thick.

Phoney Patents

Under this heading are published electrical or mechanical ideas which our clever inventors, for reasons best known to themselves, have as yet not patented. We furthermore call attention to our celebrated Phoney Patent Office for the relief of all suffering daffy inventors in this country as well as for the entire universe.

We are revolutionizing the Patent business and OFFER YOU THREE DOLLARS ($3.00) FOR THE BEST PATENT. If you take your Phoney Patent to Washington, they charge you $20.00 for the initial fee and then you haven't a smell of a Patent yet. After they have allowed the Patent, you must pay another $20.00 as a final fee. That's $40.00! WE PAY YOU $3.00 and grant you a Phoney Patent in the bargain, so you save $37.00! When sending in your Phoney Patent application, be sure that it is as daffy as a love-sick hat. The daffier, the better. Simple sketches and short descriptions will help our staff of Phoney Patent Examiners to issue a Phoney Patent on your invention in a jiffy.

Prize Winner: BALDHEADFLYSWATTER. Be it known that I, Dickson Reck, have invented a startling and withal hair-raising invention for the purpose of refreshing baldpated old ladies' and ginks' who are troubled in the summertime with the usual nuisance—flies. My apparatus, which is simplicity itself, operates as follows: A small but powerful mutt "A," preferably of the genius "homo gazabo" is caused to run perpetually after the bone "B," on a tread power, said tread power being connected by means of a suitable belt to a series of cups mounted on an endless belt. This belt carries the cups around thru a tank of water, and the cups as they reach the maximum of their upward movement, discharge the water into a basin "D," which allows the water in it to ooze thru a nozzle onto a water turbine, "E." The water discharged from the turbine passes thru a shoot and back into the original water tank. The turbine "E" is belted to a flexible rubber fly-swatter "F," which when not busy killing flies and other insects, causing them to fall into the combination fly-container and cuspidor, is caused to massage the owner's baldpate with his choice brand of hair tonic. The belt from the top of the water bucket holst, connects with the ham bone "B," to make it wabble thus irritate the mutt "A" more efficiently. Inventor, Dickson Reck, Gary, Indiana.

COLLARBUTTONFINDER. Behold my latest and greatest invention! An automatic electric collar-button-finder or retriever which should be a boon indeed to all bachelors; not to mention the married gents, whose wives regale them periodically and regularly, especially on bright Sunday mornings, with long-winded exhortations and admonitions to "get out at once for church." Zipi goes that infernal collar button under the bed, of course. I provide herewith a guaranteed retriever for all unruly collar buttons, involving an automatic electric vacuum cleaner which is connected with a series of openings one foot apart all over the boudoir floor. Storage battery connects with the lighting rod on the house and is charged free. The storage battery runs the motor, and the motor runs the vacuum pump. Zipi goes his button—Wham! goes the electric switch, and Presto! comes the button from the trenches right into your jewelry tray.—Inventor, Franklin Kral, Washington, D. C.
ELECTRICITY

The "Oracle" is for the sole benefit of all electrical experimenters. Questions will be answered here for the benefit of all, but only matters of sufficient interest will be published. Rules under which questions will be answered:

1. Only three questions can be submitted to be answered.
2. Only one side of sheet to be written on; matter must be typewritten or else written in ink, not penciled matter considered.
3. Sketches, diagrams, etc., must be on separate sheets. Questions addressed to this department cannot be answered by mail free of charge.
4. If a quick answer is desired by mail, a nominal charge of 25 cents is made for each research work or intricate calculations a special rate will be charged. Correspondents will be answered.

ARC WELDING OF RAILS.

(947) Lewis F. Bailey, Spartanburg, S. C., writes the Oracle:

Q 1. He asks several questions relative to arc welding.

A 1. Your information is at hand; such a welding scheme is quite possible, but you have forgotten to mention the voltage, etc.

ELECTROLYTIC GAS PRODUCERS.

(949) John L. Shaw, Hickman, Ky., asks several questions concerning the electrolytic gas producer.

A 1. If an electric spark is past thru the medium wherein oxygen and hydrogen are mixed, the gases are instantly hurled through the entire area.

Utilizing the Intense Heat of the Electric Arc Steel Rails and Plates are Now Welded by This Method.

However, the general method is to ground one terminal of the apparatus as shown in the accompanying diagram, and the other terminal is usually of steel or carbon, depending upon the particular case for which you desire to use it.

If you refer to the article on the Electrical Furnace in the April, 1918, issue of this journal, you will obtain some idea of the use of electrodes to be used.

We make note of a particular case where in the railway companies use an electrode of steel and the rail as the other electrode, and whereby the arc causes the metal to be welded to the rail, which is the other electrode.

COMPUTING CAPACITY OF CONDENSER.

(948) R. Howell, Los Angeles, Calif., asks:

Q. 1. About the size of secondary capacity for one-inch spark coil and how to compute the area of dielectric required.

A 1. The value of the capacity for use across the one-inch spark coil secondary should be adjustable to .02 m.f., and should consist of about 2,000 square inches of tin-foil placed between glass plates at least 1/5 of an inch thick. Below is given the formula for calculating the area of active dielectric:

area = \frac{t \times C \times 10^4}{K \times 2.248}

Where: \( t \) = thickness of dielectric in inches.
\( C \) = dielectric factor.
\( K \) = capacity in micro-farads.
Area in square inches.

mass, which will cause a sudden increase in volume, or in other words an explosion will take place.

An extensive article covering a new invention which utilizes the electric current to decompose the water so that the hydrogen gas can be used for an explosive mixture in connection with engines for autos, etc., was given in the June, 1917, issue of the ELECTRICAL EXPERIMENTER. The rate of production of these gases depends upon the area of the electrodes, the amount of current flowing, the resistance of the electrolyte, etc., and it must be borne in mind that by properly adjusting any of the above values, we can maintain a constant production of gases.

RADIO TROUBLES.

(950) C. Vetter, Wessington Springs, S. D., writes the Oracle about several radio problems which are puzzling him. We advise him as follows:

A 1. The Tigerman vacuum tube to our mind is as good as the rest of the tubes from our experience. This tube can be used with good results as an amplifier.

A 2. The appended diagram shows the connection for two-step amplification. For one step amplification, leave out the third Audion circuit and place the telephone receivers where the transformer \( T_1 \) now is. A 3. We herewith give dimensions for several types of loose couplers. (3,000 meters.)

Primary 5" long x 4" dia. with No. 24 or 26 S. C. C. Secondary 4½" long x 3½" dia. with No. 28 S. C. C.

The secondary should be wound with No. 34 (Audion circuits.)

6,000 Meters

Primary 8½" long x 5" W with No. 24 S. C. C. Secondary 8" long x 4½" W with No. 30 S. C. C.

The secondary should be wound with No. 34 (Audion circuits.)

12,000 Meters

Primary 11" x 7½" with No. 24 S. C. C. Secondary 10" x 7" with No. 30 S. C. C.

The secondary should be wound with No. 34 (Audion circuits.)

Two-Step Amplification with the Tigerman Vacuum Valve and an Audion Bulb

We use finer wire on the secondary because by doing so and with a given number of turns, an increase in volume is obtained, the induced E. M. F. being propor-
Free Test Lesson in Draftsmanship

Special offer now. Pay nothing for this Test Lesson in Drafting prepared by the experts of the Chicago Technical College. Learn from a study of this lesson how well qualified you are to take up drafting as a profession. Also see from it how clearly the Chicago "Tech" Course in Draftsmanship explains every point—and how it will give you a practical training in Architectural, Electrical, Structural Steel, Machine Drafting or any other branch of Drafting in which you may be interested. No charge whatever for this Lesson. We invite every ambitious man to send for it. To ask for it places you under no obligation. Get it while the offer holds good and let it show you whether or not you are a man who can study this technical calling to advantage. Just sign and mail coupon. Send no money.

$2500 to $10000 a Week

Positions are always open to competent draftsmen and the war conditions are sure to create an extra demand. These positions pay good salaries and the well trained man always has the best opportunity for advancement. Our course gives this training in the shortest time consistent with thoroughness. Its practical value is proved by the success of our graduates. If you are in a position where the future looks doubtful, if you want to be a technical expert, if you want to be master of a calling which will make you independent, at least get the Free Lesson and the information we send upon request.

Come to the College or Study at Home

You need not leave your present occupation to get this expert training in Draftsmanship. We will teach you by mail and you can study at home in your spare time. The work is the same as given in our Day and Evening Classes at the College here in Chicago. Your instruction will be given directly by men who are engaged in the very work they teach. They will teach you how to do just what is being done in the drafting rooms of big organizations where Chicago "Tech" graduates are always in demand at good salaries.

Easy Payments

Pay for the course as you go along. The fee is so small the terms so easy that no matter how moderate your income may be, you can afford to get this training in Draftsmanship which will prepare you for an important paying position. Catalog and all particulars sent free with the Test Lesson.

See For Yourself

This Free Lesson is an absolute test, pure and simple. Send for it today. In the privacy of your home study it, then you will know for yourself whether you are proper material for a successful Drafter. Other institutions will ask for your money first. You find out later at your own expense, whether you can adapt yourself to the work and succeed in the profession.

We do not charge you one cent for the Test Lesson, either now or later. It is absolutely FREE. Nor do we obligate you in any way whatever by writing for the Free Test Lesson, so send coupon or write postal request today. If you do nothing else but secure the Free Test Lesson you will gain such valuable knowledge as will be beneficial to your life, for the Free Lesson gives the very fundamentals of Draftsmanship which are helpful to every man. Mail the coupon.

CHICAGO TECHNICAL COLLEGE
945 Chicago "Tech" Building
Chicago, Ill.

FREE Instruments

Every student of the Chicago "Tech" Course in Draftsmanship receives this set of instruments, or a cash credit in case he already has a set. We start our students at once in practical work with necessary equipment.

Builders' Course

Men in the Building Trades whether working now as mechanics or contractors should get information about our Courses in Plan Reading and Estimating. We teach men how to make money through knowing more about their business. We want to tell carpenters, bricklayers, stone masons, and other men engaged in building work about these courses. Write for Free Lesson in Plan Reading, Builders' Catalog and other instructive information.

Chicago Technical College,
945 Chicago "Tech" Building, Chicago

Without obligation to me, please send me your FREE Test Lesson in Draftsmanship and other interesting literature covering the subject indicated below:

THE ORACLE.
Thousands of skilled Electricians are needed. The demand is becoming more urgent every day. The Government is employing every one they can get which is causing a great scarcity throughout the country and big salaries are being paid everywhere. Right now is your big opportunity. Make up your mind now to prepare for one of these big jobs and then get here as quick as you can for your training.

**Earn $100.00 To $300.00 A Month**

In the Electrical business. Come here where you will be trained in these great $93,000 shops. Experts show you everything and you learn right on the actual apparatus. You work on everything from the simple bell to the mighty motors, generators, electric locomotives, dynamos, switchboards, power plants, everything to make you a master electrician. We have thousands of successful graduates. Just as soon as you have finished we assist you to a good position. We now have more positions than we can fill. Think of it.

**LEARN DRAFTING**

Skilled Draftsmen are always in demand. Our courses are thorough—short—practical, preparing a man fully to hold a position of responsibility. We have more positions than we can fill. We also have thorough practical courses in Plumbing and Heating and Motion Picture Operating.

**EARN YOUR WAY**

Many students earn a large part of their living expenses by doing a little work in their spare time. Our employment Dept. furnishes these positions without charge.

**MAIL COUPON FOR FREE BOOK NOW!**

LEARN TELEGRAPHY QUICKER—EASIER

Morse or Wireless Code

Adjustable Buzzer Practice Set

Quickly Gives You Speed—No Tools Needed—A Touch of Your Finger Adjusts It

This practice set with its adjustable BUZZER enables you to learn telegraphy, Morse or Wireless Code, in shorter time than ever before thought possible. A touch of your finger to a thumb screw gives any pitch desired to the BUZZER. Especially designed to give very clear sound of exceptionally high pitch even on ONE DRY CELL.

The adjustment of the BUZZER to any pitch is made without the aid of any tools—simply by the thumb screw. The greatest improvement in practice sets ever made—superior to any on the market. Beautifully made; mounted on substantial base.

MAGNETIC RECTIFIER Pat'd Apr. 16, 1918

$24 Complete, and up

The France Manufacturing Co., Cleveland, O.

Use "RED DEVIL" Blades

For Hardest Cutting

"RED DEVIL" Flexible Hack Saw Blades are made from Tungsten steel only. This steel gives maximum hardness without brittleness. By a special process the teeth are made extremely hard and strong, but the back is left flexible.

Every blade individually tempered. This costs extra money and takes extra time, but gives a blade that cuts practically anything without breaking, or the teeth stripping.

The teeth are milled from the black, not jumched. This is also a slower and costlier process—but gives sharp, square teeth that cut metal as easily as a rip-saw cuts wood.

SMITH & HEMENWAY CO., INC.

IRVINGTON, N. J.

THE ORACLE.

(Continued from page 336)

Ducing the magnetic field, the motion of the copper disc is retarded on the armature; in fact, the effect is sometimes so great as to stop it entirely.

You will therefore see that since your motor is thus limited, it must be done to this extent, and we advise you to shellac each plate of the armature and the field, and we are sure that when this is done the motor will run all right at the desired speed.

The running effect of the motor is not hampered much in your particular case in reference to the magnetic condition of the field poles. You state that the armature was turned down, the slots were cut in, etc. This is very bad for as you see the idea in the shellacking of the laminations is to insulate the stampings from one another, and therefore it is necessary to file off the slightly projecting sharp edges which result from such operations.

BOOK REVIEW.

(Continued from page 336)

A timely and useful book which should find a ready demand from all interested in aero matters, especially those belonging or intending to join the Aviation Section of the Army or Navy.

Much attention is given to details and the author has certainly covered his subject well. With a brief history of flying the reader progresses, step by step through the important phases of the art.

The reason why an airplane flies is clearly set forth, as well as the mechanical condition of the various conditions of the air, gravity, stability, pressure, etc.

A comprehensive chapter is devoted to the building of airplanes, covering practically every detail from the general design, wings, etc., to rudders and running gear.

The engine is discussed from every point of view, giving its theory, construction and application, with due such refinements as self-starters.

The closing chapter deals with the qualifications necessary to become a successful pilot, where to learn to fly, etc. The aeroplane's uses in the present war and interesting notes and data giving rules and regulations for obtaining a Pilot's Certificate are included.

A large appendix contains the following information: The Barometer, Table of Altitudes, The Sphygmatic Synchronized Engine, How to Make Aeroplane Calculations, and a chart showing the Organization of the Air Service of the U. S. Army.

It is a treatise on the subject of physical training, and gives in a very complete way the subject of marching, attention, exercises, and setting up exercises. It treats at the beginning on the rudiments of military requirements which are very essential. The different physical exercises are illustrated in various motions.

The chapter on rifle exercises is well presented. The illustrations therein show how the soldier of arms performs the various exercises with the aid of the rifle. The subject of gymnastics is treated at length. It includes exercises, gymnastic contests, one-legged tug of war, and the "tug." The subject of swimming is explained in a very clear manner, and the illustrations show the various motions and strokes. The authors give an excellent description of bayonet fighting.

OUR ARMY AND NAVY AND HOW TO KNOW IT. Edited by A. A. Hopkins, publish by Munn & Co., New York, 4 x 7 1/2 inches, profusely illustrated, 114 pages, lithographed stiff paper covers. Price, 50 cents.

The book is divided into two parts. In the first half of the book the author discusses the Army, and gives in the opening chapters the names of the
various organizations and the salaries of the men in the U. S. Army. Many illustrations are given of various items of the different branches of the U. S. Army to familiarize the civilian, or the man in the service with the different branches. A complete table is given of the forts, arsenals and catteries of the U. S. Army, also special army schools, officers' training camps, National Guard training camps, etc., attached to the army of the United States. A colored chart of Army insignia hat bands is also given, designating the character of service. An excellent double-page illustration showing the leading types of American airplanes is given. Several pages are devoted to different types of war medals.

The publishers of this book print it in a reverse manner, so that half the book is consigned to the Army and Navy. In the second half the subject of our Navy is taken up, and the same order is followed in this portion as the first. Various colored plates are given, showing the rank of the Navy officers. An excellent color plate on shoulder marks for line officers, and insignia of rank of naval officers which are worn on the sleeves is also shown, including the various badges in signs as worn by enlisted men. There can be very little chance for a civilian to be mistaken in determining the rank of the officers both in the Army and Navy, if he will compare this chart with the various manuals as given in this book.

EXPERIMENTAL MECHANICS.
(Continued from page 327)

predetermined diameter is reached. In order to guide one's self to cut to the proper diameter of the work, it will be necessary to use a measuring tool set to this diameter. The tool, known as the caliper, is of two types, one called an inside caliper used in measuring the inside diameters, and second an outside caliper for determining outside diameters. The latter is the one which we are interested in since we desire to cut an outside diameter to a certain value. It will be advisable at first to set the legs of the calipers to the value of the predetermined diameter. Fig. 8 shows how a pair of calipers are set on a stock and adjusted until the other leg touches the value which is required in the turned down rod. The cutting tool is caused to travel back and forth and a cut at each pass should be continued until the work is reduced in size so that it will allow the calipers to just pass over. At this point the diameter of the portion of the work is the correct diameter of the predetermined size. Don't jam the calipers over the work: feel the cut carefully. This is one of the tricks of the trade.

On very accurate jobs, the cutting tool is prevented from taking off any metal at a point where the diameter of the work is a trifle less than the predetermined diameter. The remaining metal is removed by either a flat file or else with emery paper or cloth. This is done because the knife is unable to take a very fine cut, so it is practicable to use a file to bring the work to the proper finished diameter. Never use the calipers to gauge the diameter of the work when it is revolving, as it will spoil the calipers or it may catch on the work, and may cause damage or an accident. Fig. 11, shows that a piece of turned down work is of a certain diameter and the manner of applying the calipers in measuring it.

This is the first job that the amateur should thoroly master, and he will be surprised to see how much patience and time is necessary to be given in producing a perfect piece of work. This is a fundamental job and should not be overlooked, as a number of the most important basic operations are inherent in this first job. Each and everyone of the progressive students of "Experimental Mechanics" should try his hand on this work and in the Seventh Lesson further interesting details as to "Metal Turning" will be given.

(Next installment will appear in an early issue)

"I'm as Good a Man as Jim!"

"They made him manager today, at a fine increase in salary. He's the fourth man in the office to be promoted since January. And all were picked for the same reason—they had studied in spare time with the International Correspondence Schools and learned to do some one thing better than the rest of us.

'I've thought it all out, Grace. I'm as good a man as any of them. All I need is special training—and I'm going to get it. If the I. C. S. can raise other men's salaries it can raise mine. If it can bring a better home with more comforts to Jim and his family it can do it for us. See this coupon? It means my start toward a better job and I'm going to mail it to Scranton tonight!"

Thousands of men now know the joy of happy, prosperous homes because they let the International Correspondence Schools prepare them in spare hours for bigger work and better pay. You will find them in offices, shops, stores, mills, mines, factories, on railroads, in the army and navy—everywhere.

Why don't you study some one thing and get ready for a real job, at a salary that will give your wife and children the things you would like to have. You can do it! Pick the position you want, file the application blank for the I. C. S. and we will prepare you for it right in your own home, in your spare time— you need not lose a day or a dollar in doing it.

Yes, you can do it! More than two million have done it in the last twenty-seven years. More than 100,000 are doing it right now. Join them without another day's delay. Mark and mail this coupon!

**The Manipulation of Glass Tubing in the Experimental Laboratory**

(Continued from page 324)

around the short end before trying to break it, to prevent the glass from flying and cutting you in case you haven't had a long break. Immediately after breaking, smooth off all sharp edges of the broken ends with short quick strokes of the file. This is much quicker than cutting them with emery or coarse sandpaper. The file serves the same purpose. Never leave glass tubing around the laboratory with sharp edges, for it is not as safe as you think it is, as they are broken, and save yourself and your friends from being cut.

Tubing larger than one-half inch in diameter is somewhat harder to cut successfiully. If one has a special cutter which will cut a groove around the inside of the tube it may easily be done. One way, if no center is available, is to cut a deep groove half way around the outside of the tube and then try and break it as with the smaller sizes. This method is not successful, depending on the quality of the glass.

Trying to cut very large glass tubing without a special cutter is very unsatisfactory, yet may sometimes be accomplished with a file and a hot iron. File a deep notch at the point where the cut is to be made and then touch the red hot point of a spike directly over it. Repeat until there is a tiny crack started. Then by repeatedly touching the tube just ahead of the crack with the hot iron, the crack may be led around the tube. The tube is then broken and the edges smoothed off.

The old method of breaking tops off bottles may be used to obtain large tubes from tall olive jars. Wrap several layers of string around the jar and then soak the string in gasoline, alcohol or kerosene. Light the string and just before the flame goes out plunge the jar into water. It ought to crack in a fairly circular way. In doing this, if it does not, try until it does. Keep the jar turning all the time so that the heat from the burning string may be evenly distributed.

Tubes made from bottles of this kind cannot be worked in the flame as they are made from too brittle glass, but are very useful in making certain kinds of apparatus, as for instance battery jars, etc.

**MAKING SIMPLE BENDS.**

Bends in glass tubing are progressively harder as the tubing enlarges. The entire success of the bend depends on the handling of the glass in the flame. It is not enough to stick the tube in the flame and then bend it when it gets red hot. A bend made in this manner on a cold bottle will always break and will break under the slightest strain.

To obtain a sharp bend, the narrow edge of the fish-tail burner should be used, twirling the tube rapidly until there is an even reddish white glow around the tube at the place where the bend is to be made. The tube must then be taken out of the flame and immediately bent to its proper shape. A bend of over 90 degrees cannot be made in this manner. Also the tubing must not be too hot or the result will be ruined. Remember in all operations with glass tubing that it should be heated slowly, otherwise it will crack.

After a bend has been made and before it has been cooled, it must be annealed. This is done by holding the tube in the flame, without bending it, until the edge is thoroughly softened. A bend which has not been annealed has no strength.

To all widening bends a greater length of tubing must be heated. For this we use the entire length of the fish-tail burner and proceed as we did with the sharp bend. The greater the curve or bend, the larger the tubing the larger the curve will have to be. In bending large diameter tubing care should be taken that the tube is very evenly heated through its circumference, otherwise the inner part of the tubing will be weak when it is bent. A bend of the buckled sort will not be strong, and will usually break while cooling.

Making all bends these things must be kept in mind and carefully observed. First, the tube must be evenly heated and heated over the bend, second, it must be heated too hot. Third, the bend must be annealed by cooling it down gradually in a yellow flame until it acquires a coating of soot. Fourth, the bent tube must be laid down on the mat to cool.

Bends made in the above manner may take a little longer to make than the ordinary ones; and the experimenter will be amply repaid by the stability of the bent tubes, for the bend will be as strong as any other part of the tube.

It can easily be seen that by varying the length of the heated portion of the tube, and the condition of the heat during the bending, all these different shapes may be made. In small tubing bends may be made 360 degrees if necessary. In large tubing this is not practical and four right angle bends will do the work with ease when it is bent. A bend of the buckled sort will not be strong, and will usually break while cooling.

**CLOSING THE ENDS OF GLASS TUBING.**

To close the end of a glass tube properly the end should be slowly heated for a very short distance only. While the end is melting down the tube should be carefully rotated so that the closure will be even. It is quite a common mistake of many experimenters to melt until the glass meets—but the end is not fused. The glass must be firmly fused over the end or there will be leakage thru the minute hole in the unheated portion of the glass. You will find that the closed end will be much thicker than the rest of the tube and will break easily. These faults may be remedied by first blowing in the open end just as the glass fuses, and then by careful annealing of the end by soothing. Ends are most easily closed with a blast lamp as it allows the end to close quickly enough to prevent the glass from thickening. To obtain a square end on a glass tube after it has fused, it may be pressed or rotated. If this is not done, the end may be annealed and allowed to cool. The sealing of tubes containing liquids will be described later.

(See Part II in next issue)

**POPULAR ASTRONOMY.**

(Continued from page 311)

ent members. Paths of comets pass around the sun at all angles and some comets move in their orbits from west to east while others move in the opposite direction or retrograde. The behavior of the asteroids and comets is not all explained with the theory that was, until recently, universally advanced to explain the origin of the various members of the solar system.

Some astronomers have made attempts to modify the nebular hypothesis that had been the generally accepted way for so many years in order to make it fit in with more recent discoveries but none of these claim that a theory is required to explain the origin of the solar system. Several theories have been advanced but no new theory has yet definitely replaced the old nebular theory of the noted French astronomer Laplace.

(Next installment will appear in October issue.)
ELECTRICAL ENGINEER

ALGERIA HAS IMMENSE WATER POWER SITES.
A French engineer has found 53 localities in Tunis where dams can be constructed that can be made to yield from 30 to 600 horsepower of continuous energy.

EXPERIMENTAL CHEMISTRY.
(Continued from page 325)
(b) Add some acid to the water. Notice the effervescence of carbon dioxide gas.
(c) Boil some of the water in a beaker for 5 minutes. Notice the white deposit of calcium carbonate and magnesium carbonate, which dissolved with effervescence in acids.

2. Chlorides, principally Sodium Chlorid.
Determine the amount of sodium chloride in the water, as described above, using however, only 5cc of water for the test, diluting it with a little Croton water (distilled water will give more accurate results). In this case the number of grains of salt per gallon is found by multiplying by 10 the number of cc of solution used.

3. Sulfates.—Test for these with barium chloride and hydrochloric acid. In most of the common mineral waters this test will yield a faint result.

4. Iron.—In siphon waters and in most of the table mineral waters this element will not be present. When testing Saratoga waters, however, many others where even small traces of iron are present it is generally possible to notice the brownish flakes of Fe(OH)₃ floating in the water. To prove its presence, add enough nitric acid to make the water slightly acid, warm for a minute or two, and test for (Ferric) Iron with NH₄CNS.

5. Calcium and Magnesium.—Add ammonium hydroxide, ammonium chloride and ammonium oxalate to some of the water. Result—precipitate of calcium oxalate. Heat, filter carefully, and test the filtrate for magnesium with Na₂HPO₄.

HYDROGEN PEROXID.
Hydrogen Peroxid, H₂O₂, was first prepared by Thenard in 1818, who named it "oxygenated water." Its occurrence in nature is not abundant, but it is sometimes found as traces in the atmosphere, rain and snow.

Preparation:—
Almost any acid acting on barium dioxid (BaO₂) will yield hydrogen peroxid, thus:

BaO₂ + H₂S₂O₃ = BaSO₄ + H₂O

Other reactions being:

Na₂O₂ + 2HCl = 2NaCl + H₂O
BaO₂ + H₂P₄O₆ = Ba(HPO₄)₂ + H₂O
BaO₂ + CO₂ + H₂O = BaCO₃ + H₂O

Hydrogen peroxid solution when used for medical purposes must be as free as possible from soluble salts, especially barium, and for this reason, only such acids as sulfuric and phosforic (usually both), which form insoluble barium compounds, are used.

For bleaching, oxidizing, and as a preservative agent, the Magnesium or Calcium peroxid may be used in conjunction with such organic acids as give rise to harmless soluble salts, thus:

2CH₂O₂H₂ + 3MgO₂ = Citric Acid

Mg₃(C₄H₆O₇)₃ + 3H₂O
Mg₂(C₂H₃O₄)₂

Sodium peroxid (Na₂O₂), when dissolved in water, forms the unstable meta-borat (Na₂B₂O₄), which with the carbon dioxid of the water is converted into borax and sodium carbonate.

From Wiring Bells to Chief Electrician at $5200 a Year

What Men Can Do if They Master Electricity

Thousands of men have the natural born "knack" of understanding things mechanical. Without the slightest instruction, many of them have learned how to wire bells, and other simple principles of electricity.

If these men only knew, they could quickly acquire through knowledge of every branch of electricity, rising to the position of Electrician or Electrical Engineer. This is best illustrated by the story of a young man in the Middle West who jumped from the job of wiring bells to that of Chief Electrician at $5200 a year.

This young man knew nothing whatever about the real principles of electricity. He only knew that by putting wires and batteries together in a certain way, he could make a door bell ring. He went from house to house getting odd jobs, repairing and installing door bells, and he earned anywhere between $15, and $18 a week.

This young man realized that the opportunities in the field of electricity were almost unlimited. The possibilities of electric power were infinite. He figured that the electrical profession was in its infancy in spite of the tremendous advancement that had been made in the past few years. He found that there were unlimited possibilities for positions which would fit any degree of ability he attained. He studied the problems of electricity in his spare time and soon became switchboard man for a telephone company. In a few months he became Exchange Manager, and later Wire Chief. Leaving the telephone field, he engaged in central station work as an electrician, and was appointed operating engineer. A short time after that, he was appointed Chief Electrician at a salary of $5,200 a year.

For these young men the key for the simplest electrical operations has tremendous opportunities before him, if he will only develop this knack to its fullest possibilities. And this is now made easy for 27 authorities have placed their knowledge in seven massive volumes issued by the American Technical Society of Chicago.

These seven splendid volumes contain over 3,500 pages and over 3,000 illustrations that each book alone would cost $7 x 10, and is 2" thick. Everything electrical is explained in such an easy-to-understand language, that it makes studying more like a game than like work. These volumes tell all about Elements of Electricity, Electrical Measurements—Underwriter's Requirements—Theory in Calculation, Design and Construction of Generators—Dynamo—Electric Machinery—Lighting Machinery—Power Transmission—Electric Railways—Power Stations—Switchboards and Switching—Electric Elevators—Storage Batteries—Electric Welding and Heating—Electro-Chemistry—Wire and Wireless Telegraphy. In fact this remarkable Cyclopedia of Applied Electricity explains everything from wiring bells to the newest discoveries in the electrical industry.

These seven volumes alone will enable anyone who has a liking for the work to master electricity and qualify for the big positions of chief electrician, or enter into business for himself. But with the seven massive volumes, the American Technical Society offers a full year's consulting membership without extra charge. This entitles you to the advice and help of a corps of electrical experts. Many men say this personal help has been worth hundreds of dollars to them, yet it is yours free, if you act quickly.

The seven volumes are so valuable that the publishers are anxious to send you the entire set for free. Only a few copies are left in stock, so you need send no money in advance. Then, if, after examination you decide to own them, you can exchange your set for $2 a year after receiving the books, and only $2 a month—an average of only 7c a day—until the special half price is paid.

It is not necessary to send a penny in advance. Just mail the coupon below and the books will be sent to you at once. The regular price of the seven volumes is $35, but on the present special offer the price is only $19.80 for the complete set, so you are getting a rare bargain. Remember, it is not necessary to send any money now. Just mail the coupon below or copy it in a letter, and the seven massive volumes will be shipped for free examination. The year's consulting privilege is free if you decide to keep the Cyclopedia of Applied Electricity.

American Technical Society,

“I Would Not Part with it for $10,000!”
So writes an enthusiastic, grateful customer. In like manner testify over 30,000 people who have worn it. Conserve your body and life first.

The Natural Body Brace
Overcomes WEAKNESS and ORGANIC AILMENTS of WOMEN AND MEN. Develops needed, graceful figure.
Brings restful relief, comfort, ability to do things, health and strength.

Wear it 30 Days Free at Our Expense
Does away with the strain and pain of standing and walking; replaces and supports misplaced internal organs; reduces enlarged abdomen; straightens and strengthens the back; corrects stooping shoulders; develops lungs, chest and bust; relieves backache, curvatures, ectopic curvatures, constipation. Comfortable and easy to wear.

Keep Yourself Fit
Write today for illustrated booklet, measurement blank, etc., and read our very liberal proposition.
HOWARD C. RASH, Pres. Natural Body Brace Co.
205 Rush Building
SALINA, KANSAS

NaBO₃ + H₂O = NaB₂O₄ + H₂O
4 NaBO₃ + CO₂ = Na₂B₂O₄ + Na₂CO₃

By using 14 grams of perborate for each 100 cc. of water, a 10 volume hydrogen peroxid solution is obtained.

For preparing the medicinal solution of hydrogen peroxid, barium dioxid is first hydrated: BaO₂ + H₂O = BaO(OH),
by slowly adding to it about double its weight of distilled water, ice cold, and, after standing about 30 minutes, either phosforic or sulfuric acid with water is gradually added with constant stirring, keeping cold by employing ice, until the mixture remains slightly acid. It is then made neutral by adding more of the dioxid.

Properties:
Physical:— It is a nearly colorless (slightly blue in quantity), syrupy liquid.
It possesses a metallic, corrosive taste, and pungent odor. It is miscible in water.
Its specific gravity is about 1.5.

It volatilizes at about 84 degrees F.
Chemical:— It readily decomposes into oxygen and water, even when in dilute solution, especially if exposed to heat or sunlight. Concentrated solutions are unstable, and will decompose, increasing in rapidity with rise of temperature, and near 100 deg. decomposition usually takes place with explosive violence.

2H₂O₂ = 2H₂O + O₂

Explosion of concentrated solutions may also be caused by the introduction of solid matter or finely divided platinum, iron, manganese, etc., or of oxygen.

It is one of the strongest oxidizing agents and antiseptics, and will even oxidize silver, due to liberation of free oxygen, perhaps as ozone.
Strong solutions bleach the skin white, as well as bleaching organic pigments, hair, feathers, bone, etc.

It also reduces, as well as oxidizes and is a powerful disinfectant and germicide.

Uses:
The chief use of hydrogen peroxid is as an antiseptic and germicide. While this is by far the most important use, the solution is employed sometimes by artists to renovate old paintings. Its oxidizing action adapts it as a bleaching agent for cotton, wool, silk, ivory, hair, oils, etc. It is also used for sterilization and preservation of foods. It is employed in photography to remove the last traces of "hypo" from prints. Tests:

Upon the addition of hydrogen peroxid to a dilute solution of potassium iodid con-

UNCLE SAM WANTS OPERATORS

RADIO AND MORSE

Your Government is calling for experienced wireless operators and telegraphers. Many schools have been opened where special instruction is given qualifying young men to accept such positions in the army and navy with advanced rank and increased pay.

You Can Learn at Home in Your Spare Time

Combination Wireless-Telegraphy OUTFIT

will soon make you an accomplished operator. Teaches Light and Sound Signals, both Radio and Morse. Outfit consists of exceptionally fine Telegraph Key, Buzzer, 3 Binding Posts, Lamp, Lamp Socket and Control Switch—all mounted on a highly finished base. Two outfits can be operated at considerable distance apart for sending and receiving practice.

beer September, e If ozone

Ozone HISTORY.

When a static electric machine is in use, a peculiar and characteristic odor is present. It is also observed, to a slight extent, in the air after a thunder-storm. Van Marum, in 1785, described his observations, and that he had obtained the same odor in the gas given off from the anode when alkalized water was subjected to electrolysis. Schönbein applied the name ozone, signifying a smell.

PREPARATION.

Ozone is evolved at the positive pole in the electrolysis of water alkalized with either sulfuric or chromic acid. It is also formed by the current discharge of electricity throng air or oxygen. Fig. 131, shows a tube known as Siemens Ozone Tube consisting of a glass tube covered with tinfoil, which is divided and has the larger one covered on the outside with tinfoil. The outer and inner coatings are connected to an induction coil while a current of air or oxygen passes thru.

It is also obtained when phosphorus is permitted to slowly oxidize in the air, or when oxygen is past over pieces of moist phosphorus.

PROPERTIES.

Ozone is a colorless gas with a peculiar odor, such as is noticed about moist phos-

phorus. It reverts very gradually into ordinary oxygen, which is change hastened upon heating. Ozone dissolves readily in the volatile and fixed oils, and at 12 degrees water dissolves one-half volume of the gas, which solution is gradually converted into oxygen and hydrogen peroxide, thus: H₂O + O₃ = H₂O₂ + O₂

It bleaches organic colors, such as indigo, litmus, etc., phosphorus, sulfur, arsenic, and all metals, excepting gold and platinum, are commence to react into their respective basic oxides, ammonia being oxidized to ammonium nitric. Silver is blackened through the formation of black peroxide, and lead sulfide is converted to lead sulfate.

Detection:

1. (Paper moistened with potassium iodide solution and starch paste turns blue when exposed to an atmosphere of ozone, thus:

2KI + H₂O + O₃ = O₂ + 2KOH + I₂

Other oxidizing agents, as chlorine, bromin, nitrogen dioxide, also produce this reaction.

2. Paper impregnated with a tincture of guaiac, and moistened with water, turns blue.

3. The bright surface of silver is blackened by ozone, no other oxidizing agent producing the same effect.

4. Paper moistened with a solution of tetra-methyl-diamido-dipheny1-methan in acetic acid, gives a violet color with ozone, yellow with nitrogen dioxide; deep blue with bromin or chlorine; and no color with hydrogen peroxide.

Uses — Ozone is employed in industrial bleaching processes; for the destruction of fusel oil in alcohol; for the cleansing of wine and beer flasks; and, for the sterilization of water.

(To be continued)
EXPERIMENTERS! ATTENTION!!

"ELECTRO" LOUD-TALKER

We present herewith two little instruments for which we have had a long and persistent demand. This outfit has been gotten up solely for the Experimenters and for this reason we are selling it "Knocked Down." In other words, the instruments come all ready for you to assemble, all the parts, screws, nuts, washers, etc., being furnished. Complete directions how to assemble accompany each set. With a pair of pliers and a screw-driver, the outfit can be readily put together in less than twenty minutes.

The most important point is that the telephone receiver spool comes already wound complete, and the Experimenters will, therefore, not need to wind his own spool.

The outfit when assembled comprises a highly sensitive CARBON GRAIN MICROPHONE with carbon diaphragm of exactly the same type as is used with our $15.00 Detectophone. (See our Cat. No. 19.)

The receiver is a special low resistance double pole type with the difference that no magnet is used in the same for the reason that the function of this instrument is electromagnetic, the same as all loud-talking phones.

The spool is wound with special enamel wire for five ohms, standard with our Detectophone.

This instrument works best on four dry cells, and particular attention is called to this fact. In order to work, the loud-talker requires a fairly heavy current, and for that reason thick wires must be used for connecting the transmitter with the loud-talker. If this is not done, the voice will be weakened considerably. If no heavy wire is at hand, more batteries must be used to compensate.

USES: This instrument can be used to transmit phonograph music from one room to another; used as a Detectophone; as a Radio Amplifier; as a telephone extension (by placing the regular telephone receiver against the sensitive transmitter with the loud-talker); for salesmen to talk "through" window (Loud-Talker outside in street, microphone transmitter for salesmen, talking into same); for restaurants for talking to the chef, and a hundred other uses. Many young experimenters are developing a lucrative business selling this appliance to various merchants at a good profit.

Outside of the two instrument parts, one hundred feet cord is furnished with sensitive microphone as shown; instructions, etc., are furnished.

No. AEK044 "Electro" Loud-Talker Outfit, Parts, "Knocked Down," complete...........
No. CEK035 "Electro" Loud-Talker Outfit, same as above except that it is already assembled and tested at factory.$3.50

Immediate Shipments

S. O. S.!! A REAL ELECTRIC Learner's Telegraph Outfit for 25c Prepaid

In the 15 years of its existence our company has never offered such a bargain as the present one. Just think of it—a real electric learner's telegraph outfit with which to learn the code or to telegraph to your friend six blocks away, for 25 cts.!! Impossible—you say. Quite so. We do sell them at cost, but we do it solely to get you acquainted with us and place our wonderful catalog in your hands. And if this telegraph pleases, you will order other things from us. This telegraph has a red-lacquered wooden base, strong electromagnet, nickel binding posts, generous telegraph knob and nickel clacker. Telegraph measures 3½ x 1½ x 1½" over all. Full directions how to learn the code, and a fine CODE CHART go with the telegraph, all packed in neat box. Telegraph works easily on a single dry cell. Two instruments may be ordered for 50 cts. If wanted, to telegraph between two rooms or two houses.

25c

"THE LIVEST CATALOG IN AMERICA"

Our big, new electrical catalog No. 19 is waiting for you. Possibly the most complete electrical and mechanical catalog in print today, 500 Big Pages, 500 Illustrations, 500 Instructions and apparatus etc. Big 8” x 11” size. 100 Free Articles, 100 Free Outlines, 100 Free Pictures, 100 Free Plans, 100 Free Ideas, 100 Free Outfits, 100 Free Catalogs. For the price of a postcard, you can get it. Send name, address, and postal for your copy of "THE LIVEST CATALOG IN AMERICA"

Now before you turn this page write your name and address on coupon at right. Cut out, fill in, and mail to Electro Importing Co., 231 Fulton Street, New York City.

UNCLE SAM NEEDS THOUSANDS.

Important. As this telegraph is sold at cost, we reserve the right to decline your order (by refunding the money) unless you order at least one from our free Cyclopedia Catalogs at the same time. Should you already have our Cat. No. 19, it is necessary to cut out the coupon, writing across it: I have Cat. No. 19. This is done for the guidance of the despatching department. Of course, if you have Cat. No. 19, you need NOT send for it again.

We are prepared to fill orders for 10,000 of these telegraphs this month. They are in stock NOW. Your order will be filled within 12 hours.

The Einthoven Galvanometer, Its Theory, Operation, Construction.

(Continued from page 319)

No. 30 drill, and are used to take out the leads from the winding. Core the ball end is carefully shelled and covered with two layers of paper for insulation. The bobbin is then wound evenly, full with No. 24 double cotton-covered magnet wire. Leads are carefully removed from both ends and properly secured so as to prevent them from breaking off at the ends. The magnet yoke is made from wrought iron bar and its lay-out is given in Fig. 7. It is very essential that the drilling should be very accurate and dimensions carefully followed, as the accuracy of the whole instrument assembly depends upon the drilling of these few holes. After the coils are wound they are then set in the respective holes in the yoke and firmly secured therein by set screws or by a close fit.

The active magnetic pole pieces 5, 5a are used for concentrating the magnetic field in the string region, and Fig. 8 shows their construction. They are also made from wrought iron. Altho their shape may seem peculiar, yet it was found thru actual test that the magnetic field was strongest with this type of construction than with any of the others that were tried. These pole pieces are fastened to the electro-magnet pole pieces by means of 8-32 set screws as noted. Two auxiliary pole pieces 6, 6a are used to increase the magnetic path service and also as a means of supporting the viewing telescope. Their details are given in Fig. 9. The telescope hole is drilled to receive a three-eighths inch tap. This should be of No. 40 thread pitch.

The movable wire-supporting stand 7, is made as shown in Fig. 10. It is composed of a solid brass rod three-quarters of an inch in diameter and cut to size with two 8-32 tap holes at each end as indicated. This is secured to the wood base, and a projecting arm 8, Fig. 11, is used to support the wire containing tube 10. It is made from stock brass measuring 3-5/8x7/8x1/8, and the two holes are made at each end, one 7/8 and the other with a No. 18 drill, as shown in the figure. A tension controlling tube 10, is inserted in the 7/8 hole, and this is made as indicated in Fig. 12. The 4-32 tap hole is used to secure a notch piece, Fig. 13, to prevent the tension rod Fig. 14, from turning when it is tightened or released. This rod is made from a No. 10 brass rod. One and one-half inches from the end, cut a three-sixty-four inch slot, three-sixty-fourths of an inch deep. This can be done easily without either a shaper or milling machine, by taking two hacksaw blades and securing both of them in the hacksaw frame. Care should be taken that the teeth of both be in the same direction. The rod should be firmly secured in a vise.

**POPULAR DEMONSTRATION OF THE THOUGHT TRANSFERENCE AND OTHER PHENOMENA.**

(Continued from page 304)

To note the action on the pulse over a great distance, suspend a coil of wire from a room fixture (aerial) and to the latter connect a wire (see experiment III and Fig. 3) with the pit of the stomach of percipient (overcloth). If you are not willing at a distance (in the percipient's direction) the latter may be informed over the telephone the moment he wills by another who announces the fact the moment the pulse of the percipient is retarded. I have successfully conducted this interesting experiment at a distance of 41 miles.

**EXPERIMENT II.**—Showing the effects of concentrated thought. When sudden concentrated thought (arithmetic problem) is executed, some agents may influence the pulse but all may do so if RED MATERIAL is placed on the agent's head.

Note the influence of different colors on intense thought or willing by the agent. RED and PINK, or RED and PURPLE decreases the effects of the pulse.

**EXPERIMENT III.**—Showing that concentration of the mind is literally true. To prove this brain focusing, let the agent concentrate the mind on one of several wooden or paper objects in the room. One end of a...

We give full training in our proposition.

SOLD ON GENERAL TRIAL PLAN

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.
hands are extended at the latter site, no effect on the pulse can be noted until one hand is removed. The human is essentially a battery, and the finger tips of one hand positive electricity is discharged and from the other hand, negative electricity. One electrical action on another female and therefore, no energy evolved until one hand is removed.

The vibrations from the hand cause a contraction of the heart (reflex) which is practically telekinesia on a small scale. Note that, with subdued light the energy from the fingers will cause normally no effect at all. If a magnet is placed opposite the fingers, it is seen that the energy is there, but no concomitant action on the pulse at a further distance than in the light.

Man is a transformer of energy which be, however, in various parts of the body. It is noticed that the pulse effects are greater after exposure of your body to an intense light or a charged magnet than before it.

Note that when several persons grasp hands and one of the persons presents the fingers of his disengaged hand at the pit of the stomach of the percipient a greater affect is noted.

EXPERIMENT VII.—Showing that polarity is a matter of magnetizer of magnetic materials. On either side of the windings in the neck, (Fig. 4) are the right and left pneumogastric nerves. When these nerves are reversed, the normal movements show less amplitude and when they are deprest the movements show greater amplitude.

Fig. 4.—Lines indicating the site of the right and left pneumogastric nerves.

Take a bar-magnet (held at end with fingers at right angles and directed at a right angle) into a following effect on the amplitude of the needle:

**MALE**

Right Pneumogastric Nerve—
Positive pole (N) Increases amplitude
Negative pole (—) Decreases amplitude

Left Pneumogastric Nerve—
Positive Decreases amplitude
Negative Increases amplitude

**FEMALE**

Right Pneumogastric Nerve—
Positive pole Decreases amplitude
Negative pole Increases amplitude

Left Pneumogastric Nerve—
Positive Increases amplitude
Negative Decreases amplitude

Note that the foregoing refers only to the normal male and female. If, in a male or female, the polarity is reversed, the male would react like a female and vice versa. Sexual inclination is a matter of polarity and its determination may thus be demonstrated. A mistake in your deduction is a serious matter. Note that the extended finger tips of the right hand of a normal male directed to the pneumogastric nerves act like the positive pole of a bar-magnet whereas the fingers of the left hand act like the negative pole. The opposite holds good in a normal female. Note that Yellow Material, on the head or body of a normal male or female, will reverse the polarity of their finger tips. That is, the male will show female and the female, male polarity.

Changes in influence sex tendencies. Show effects with the positive or negative end of any dry cell like with the magnet. Phoebe's case experiment will suggest themselves to the interested experimenter. Remember, however, that the most mystifying phenomena rest upon the least clear explanation and the simpler a thing is, the harder it is to understand. Observe all the details as suggested. To demonstrate phenomena which have heretofore baffled the scientific world is at least worthy of patience.

**ELECTRICAL EXPERIMENTER**

**THE GYRO-ELECTRIC DESTROYER—ONCE MORE.**

(Continued from page 313)

I urge you to make the attempt. You have the journey and it won't cost a whole lot to make the attempt. The result might astonish you, and if our joint efforts could shorten this struggle one month, even the money would be well spent.

Why not go to:

CHARLES S. WOLFE,
1200 Stammb erg St.,
Norrhistown, Pa.

All of the letters received read practically alike, but the strangest part about the whole story is that it is in correspondence with certain U. S. Senators, to whose attention I had brought the Gyro-Electric Cruiser, I had never thought about bringing up again and subsequently turning it over to Uncle Sam.

But, EXPERIMENTER readers evidently know and sense more than I, with my nose to the everlasting grindstone, so if my reader-friends desire to wish a new job on me—well I can only say that they will find me not to be capricious.

It is quite an idea at that, and I am glad it did not originate with me. I'd much prefer the "other fellow" endorse the scheme.

Besides, Readers, wouldn't it sound good if, after the War, we could say, casually, "I am the Gyro-Destroyer. Yes!" My dollar went into the first one—and that dollar proved SOME fighter!"

Here's my plan: A small model about 10 feet high and $8,000, figuring materials, labor, engineers, shop equipment to build it, etc. A half "life" size model, (20 feet high) would cost as much as $20,000. But what is that for 100,000 readers? Let every reader send in his contribution of any amount he can afford and we will build a model. The total amount received enables us to. If every reader contributes $1.00 we can build a complete full size Destroyer to turn over to Uncle Sam. It is self-understood that I must account for every cent taken in as well as spent. Each contribution will be printed in the magazine, as well as a final statement showing how the money was spent. If less than $5,000 is taken in the money will be returned to its owners. If a sufficient amount is collected a real working model will be built as fast as it is possible, and while EXPERIMENTER readers will be kept informed as to the progress of the Destroyer.

As soon as it is completed it will be formally turned over to the War Department in the name of the readers of the Electrical Experimenter, while a printed list giving the names of the contributors will be furnished the officials at the same time.

Now you know the arguments of the case. Judge for yourself. If you close remember that in the February issue, for military reasons, I did not divulge certain important features which tend for great efficiency of the Cruiser. I furthermore did not divulge a very important protective feature, to prevent the Destroyer from being bombed from aeroplanes above. All these features would of course be incorporated into the model, and as we would no doubt be able to obtain Government contracts for the same, when the model was being built, there would be little chance of important information leaking out.

Now, the Gyro-Electric Destroyer is in your hands. Don't be afraid to annoy us, with a stereotyped patriotic appeal urging you to sign the appended blank. As a matter of fact, I do not wish to urge you. It is entirely a matter of your judgment and whether you believe in the Destroyer.

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.

**Be a Doctor of Chiropractic**

Build a successful career in this great profession—Chiropractic, the non-invasive method of treating disease through spinal adjustment. The demand for Chiropractors is constantly increasing. In larger numbers than ever before intelligent, thinking people are becoming convinced that it is the common sense and really scientific way to relieve pain and disease.

Learn At Home under the personal guidance of practical Chiropractors. You can master this fascinating profession and graduate with the degrees of Doctor of Chiropractic while holding your present position. No special preliminary study and no more than a common school education are required. The cost is small—terms easy.

$3000 to $5000 a Year

The success of many Chiropractors has come so quickly as to be almost startling. incomes of from $3000 to $5000 are not rare—some upwards of $10,000 a year. Dr. R. H. Jones of Kentucky reports $5000 a year; Dr. L. H. Hoche, New Jersey, $3000; Dr. Hanso, New York, $1500. The point is this: you receive the same kind of instruction which these Chiropractic readers have received, and the reason why you should not do as well or better.

22 FREE Charts in colors. Actual value, $15.00. Send them all free. Send coupon for facts about this Free offer—also see free page Book which tells all about Chiropractic and its wonderful possibilities. This is your big opportunity to enter a dignified profession, be your own boss, be honored in every community where the American people will go. 1000 will pay for the same Book. A coupon today.

"EXPERIMENTS" $1.50

By E. De Moll

P. EDELMAN, Feb.

1002 Hague Ave., St. Paul, Minn.
Submarines, torpedoes, flying machines, machine guns, immense howitzers, the British "tanks," and an untold number of other products of American brains, are dominant factors in the Great War. We are just starting, our "OOR--ingenuity" must lead to much, Uncle Sam—the whole civilized World—is seeking ideas that will aid in the fight. Can't you help with even a single idea, or thousands of simple things that will win recognition—perhaps fortune for you?

The need for invention of peace, too. Never before was there such a demand for new ideas of all kinds, however before by inventors, and other patent buyers, written me for good things protected by OWEN PATENTS. There is, to-day, a market for thousands of ideas, including YOURS. Write for my free booklet and see—read for yourself the hundreds of requests recently received.

You incur no obligation by writing me. My advice costs nothing and I make no charge for an opinion as to patentability of your idea. If my opinion is favorable I will back it up by a Guarantee Contract which protects you fully. If you want to sell your invention, I will help you, and will advertise it, tree of charge, in "INVENTION AND MANUFACTURING." A simple request will bring you to one of my free four books—"SUCCESSION FUL PATENTS," a 72 page guide telling how to proceed, gives references, etc.; "STRESS STONES" tells the truth about prizes for inventions, gives hundreds of hints of inventions wanted, etc.; "PATENT ROYERS" publish over 4000 inventions; "The Patent Inventor" and "The Patent Inventor's Guide" for inventors who want OWEN PATENTS, together with ideas they want; "PATENT PRO- MOTEUR" tells you how to sell, why inventors fail, discusses the value of your idea, etc.

Write for these books to-day. I will send you a signed agreement that will protect you before you disclose your invention.

RICHARD B. OWEN, Patent Lawyer

ELECTRICAL EXPERIMENTER

GOVERNMENT TO CONTROL ALL WIRE SYSTEMS.

A bill to authorize the government during the war to take over control of all telegraph and telephone communication, cables and wireless stations, was recently signed by President Wilson.

The National communication lines went under Government control on July 31. It is reliably reported that the control will include telegraph, telephones and cables. The radio systems of the country already are under Government supervision.

ELECTRIC FURNACE TO MAKE WAR ALLOYS.

Plans for the erection of an electric furnace in Spokane, Wash., for the production of alloys for war uses, on a site to be furnished by the Washington Power Water Company, which is also to furnish the power for the experimental purposes, were discussed at a recent meeting held under the auspices of the industrial committee of the chamber of commerce. Those present pledged $1,000 toward the $2,000 needed. Washington State college has pledged $500.

As a symptom of the recent rapid development of Japan's commercial interests in Shanghai, Japanese lighting interests are now supplying a large proportion of the electric lamps for the city which were formerly imported chiefly from the General Electric Company in America. The fact is pointed out in the report of the Japanese consul-general at that point.

H. GERSNSBACK

A. Nothing of this kind is patentable. We presume our correspondent refers to small trench tanks which are sent out over "No Man's Land," the motion being controlled by a cable or wire. Quite a good subject of this kind have been proposed, but unless there are unusually new features connected with it, we doubt if a patent could be obtained.

Linotype Gas Lighter.

(255) Walter Lichtenberg, Tacoma, Wash., submits a diagram and sketch of an electric automatic linotype gas lighter, the idea being to have it controlled by a clock so that the gas could be turned on at a certain pre-arranged time in order that the linotype operator would not have to wait until the metal is molten.

A. This scheme is very clever, but we are quite certain that no patent can be obtained because there are no new functions contained in this idea. It is merely an adaptation of well known as well as old principles towards something that may not have been done before.

Phonograph.

(256) J. Brenton Berry, Orangeburg, S. C., thinks he has an idea whereby the volume of a Victrola can be greatly increased and the music be made more distinct. He thinks that by attaching a small piece of expanding or some such material to the arm to which normally the phonograph needle is attached, the sound will be greatly increased.

A. From the sketch and description which accompanied this article, we fail to see any greater volume of sound should be obtained by this system. All phonograph sound boxes are a microphone for reproduction.

Street Car Indicator.

(257) Gerald Lyons, Cleveland, Ohio, submits a diagram and description of a street car indicator. The idea is to have a ratchet wheel driven by a protruding notch placed on the rail. Every time the ratchet wheel hits this notch, a drum will be advanced which shows the street indicated.

A. There is nothing intrinsically new about this idea, and the worst feature about this is that schemes of this kind have always been looked upon with great disfavor by the traction companies, for the reason that anything that tends to interfere with the regular operation of their standardized equipment is not popular. It would also be more or less as useless for vehicular traffic, to have an abundance of notches of this kind on rails going thru streets, etc.

Air Compressor.

(258) G. Clarke, Toronto, Can., submits an idea of a complete air tank system whereby a large...
ELECTRICAL EXPERIMENTER

NEW SERVICE for INVENTORS

I personally report upon, prepare and prosecute every case submitted to me. I give every case my closest personal attention. I do not entrust your file to inexperienced assistants. My personal service on your invention is of vital advantage to you. This is new efficiency, new promptness in patent service. I report on your case in two days. No longer than 10 days to prepare your case for filing. Send sketch or model for prompt search and report.

PATENT KNOWLEDGE for INVENTORS

Free by mail my new 90-page booklet, "Electrical Experimenter." A volume of real information on patents. Different from the usual "Circus Stuff." Contains startling information usually not told. Write for this free book today. It will open your eyes.

Can You think of a simple, practical idea that will fill one of the many gaps in our inventions? It may be a fortune for you. Thousands of things are needed right now. Your brains can help. Send today for our great new book—"Inventions and Trade-Marks Their Protection and Exploitation" and learn more about making money from ideas than you ever knew before. It tells many things that are wanted. A postal will do— It is free.

We Help Our Clients without charge to get the dollars out of their ideas—having facilities none others possess. Advice free. Don't delay—get the book at once.

automatically cuts off the electric current from the motor as soon as the speed becomes too high. This scheme is readily understood by studying the attached diagram. Our advice is asked as to patentability, etc., and if the scheme is feasible.

A. While the specific means to cut off the current as shown in the diagram is new, the general underlying principle is quite old, as nearly all compressors work on a principle of this kind, and particularly those used on elevated and subways trains. Usually a gage is made use of which has two diaphragms, the latter, when expanding, makes or breaks the contacts. It appears to us that the scheme as outlined by our correspondent seems somewhat more complicated than the existing means of this kind.

Bicycle Brakes.

(259) G. L. Koch, Braddock, Pa., writes as follows:

I have an idea for an emergency brake to be used on bicycles, to keep the right side of the front wheel tightly clamped. Such brakes could be made and sold for 25 cents.

A. There is nothing new about an idea of this kind, quite a number of bicycle brakes of this sort being in existence now.

New Ideas. Inventors, send for our "Blank Form of Disclosure" that will Protect you until your application is filed in the Patent Office. Our book "Making Ideas Pay" gives full information, relative to securing protection. Manufacturers are writing us continuously for new inventions. Send for Book and Blank Form of Disclosure today. Prompt service. Best results.

magnet (see Fig. 83-1). (See Lesson 12.) We could easily have predicted this result for can we not consider the helix to be many of the discs of the preceding experiment placed together? When this series of discs are placed side by side all the poles are neutralized except those at the two ends; since in the other cases a N pole is in contact with S pole. This is obviously analogous to a bar magnet. The right-hand rule slightly modified as follows is convenient in determining the direction of the field of a helix, knowing the direction of the current and vice versa. GRASP THE HELIX IN THE RIGHT HAND SO THAT THE FINGERS BEND UPRIGHT IN THE DIRECTION IN WHICH THE CURRENT IS FLOWING IN THE WIRE. THE THUMB THEN POINTS IN THE DIRECTION OF THE NORTH POLE OF THE HELIX. IF THE HAND IS PLACED SO THAT THE THUMB POINTS IN THE DIRECTION OF THE NORTH POLE OF THE HELIX, THE FINGERS WILL SHOW THE DIRECTION IN WHICH THE CURRENT IS FLOWING. (See Fig. 83-1.)

The writer suggests that the reader test himself on the knowledge of these important rules by considering the battery so as not to know the direction of the current and determine the direction of current flow, and also by removing the compass and determining the polarity.

(To be continued)

GENIUS AND ULTRA VIOLET RAYS.

(Continued from page 296)

his imaginative power together with his cheerfulness. At the day declined his mental activity diminished until he fell into a lethargy which lasted to the following day. "Giordani could only compose in the sun, or in the presence of abundant light and great heat." There have been also many geniuses who could compose only in the presence of great heat. Sylvester, a great mathematician, tells how when on board the "Invicta" beneath the vivifying rays of a powerful sun, the method of solving a multiplication problem occurred to him, and he succeeded without pen or pencil. Many other examples could also be cited but the reader can refer to them himself in many biographies.

We then see that not only is the sun the "all life giver" but that he has aided geniuses in their creative works by means of its ultra violet rays acting on the cerebral substance as stimulants.
The "Electro" Radioiote
HIGH FREQUENCY SILENT TEST BUZZER
This instrument is a wonderful high pitched MUSICAL NOTE in the receiver, immune to static with the ordinary test buzzer. The RADIOIOTE is built about entirely new lines: a tubular form of the "Electro" an ordinary commercial instrument. The RADIOIOTE has a more powerful coil, which is set at a high speed, adjusted to its most efficient frequency in the factory. Plated contacts are used to make the instrument practically forever.

The "Electro" Codophone (Patents Pending)

What is the Electro Codophone?
A. It is a telephone receiver equipped with a horn, so loud that you can hear the distant end of the line within 30 feet. That's all of it.

That's Not All. By leaning or tilting the receiver, can be used for intercommunication between two homes one-half mile apart. One end code replaces the old-fashioned learner's telegraph set, consisting of key and reproduced in a wireless. The complete outfit is furnished: two handlers made instrument, foot proof, and built for hard work. The handles are of hard silver to inch in diameter, and that will last you forever. There is also a code chart and full directions allowing any intelligent young man or girl to become a wireless operator in half an hour a day.

The "Electro" Codophone as described, complete... $1.50

$1.00 ELECTRICAL ENGINEER'S HANDBOOK

ELECTRICITY!

Here's just the book on Electricity that you need to answer your many questions—over 1,000 pages of problems, to teach you new kinks, to be your memory for tables, formulas, and other electrical and mechanical facts that some people try to call "standard"—and fail!

With this "Little Giant" I.C.S. Electrical Engineer's Handbook in your pocket, you can work over your workbench, drafting table, desk, or anyplace until the last minute, with no fear of losing any of your work, or of not being able to find the answer you need.

No Risk Money-Back Offer!

The price of the famous I.C.S. Handbooks, of which more than 25,000 have been sold, is only $1.00. The copy of this handbook, which includes the contents and construction that you are sure the authors will give, and the copy of any I.C.S. Book is returnable to the publisher, and you will be refunded the full price of the book, if after using it for a few days you are not satisfied. Simply send a letter or copy the cheaper to us, enclosing five cents, and the book will be sent you.

$1,000,000,000 PERPETUAL

By GEORGE H. ROBERTS

The Electrical Engineer's Handbook is one of 22 I.C.S. Handbooks covering 52 Technical, Scientific and Commercial subjects. It has been estimated that only 10 per cent of these subjects have been included in the Handbook. These books have the contents of a full-size book condensed into a pocket-size book. They are ready to go with you anywhere and everywhere. They are of value in the field, cabin, on streets, in your pocket, red edges, goldLeafed stamping, printed from new, lovely, reusable type on good book-paper and illustrated wherever a picture will help.

CORE WIRE

We have been fortunate in securing thru auction several tons of guaranteed pure, double annealed Norway Iron Core Wire and are sending this wire to "Experimenter" readers.

AT PRE-WAR PRICES 20cts LB.

This wire is just the thing for spark coils, transformers, etc., and it is, of course, a very much more superior product than the usual iron wire. We absolutely guarantee the quality.

If you ever thought of building a spark coil, transformer, or similar apparatus, now is the chance to get the right material for it. As far as we know this is the only lot of Iron Norway Core Wire in the hands of any dealer at the present time, and none can be gotten until after the war.

We have these three sizes:

24 INCHES
26 INCHES
36 INCHES

Thickness about No. 21 B and S

If either of these sizes should be too long we advise cutting the wire down yourself by means of shears. You will pay you to do so as real Norway Iron Wire, sold by a few dealers last year, brought from 40c to 50c a pound. American core wire now sells for from 30c upwards per pound.

As long as the supply lasts we offer this wire as described above to our customers at the very low price of 20c a pound. Order at once.

producing pictures in their natural colors, and for many years made most exhaustive experiments to develop a theory which he had formulated when he first began this work. Success has been attained, and the pictures show how faithfully the invention is able to reproduce in color tone, shade and tint of the colors of nature.

The process is not only practicable, but is comparatively inexpensive and simple. By means of a small disc of radium and a color screen attached to any motion picture camera, several color values of the image photographed, are given to the screen, from which positive frames are printed by a secret chemical process. A film is thus produced which contains a series of images so colored as to give, when projected, a moving picture in natural colors, without the use at all of the rotary colored shutter which is usually required. By this contrivance, the brilliance and intensity of the projected colored picture is increased and a stereoscopic effect is obtained, impossible in black and white. There is no more light required than is used in projecting white and, a speed of only 24 to the second is required; thus certain experiments being made, this speed will be reduced. The cost of the film, which is, by this process is slightly more than that for making black and white ones, while the one reproduced in the Radium Furnace moving motion pictures is considerable.

The effects obtained are marvelously true to nature. The range of tints and hues unlimted. The presence of grays and neutral tints which are always present in nature, and which soften and tone down the harsh colors, are plentiful in these pictures. Thus, in addition to showing the vivid colors, all the delicate shades and hues of flesh tints, of cloths and draperies, of the gradually changing sky tints of sunrise and sunset, are reproduced with magical subtlety.

The author had the pleasure of seeing the new wonder pictures and they certainly merited the frequent applause, as each new possibility was unfolded on the screen. In order to bring out all the beauties of these three charmingly clad young women in Greek garb danced on a lawn, and the pictures showed wonderful coloring, the trees, lawn, bushes, and soft natural hues of the girls' costumes hung beyond comparison. Then followed the scenic wonders of Yosemite Valley, Yellowstone Park, Brehal Real Veil Falls, the pleasing bathing girl pageant at a southern Californian resort, all in natural colors.

MAKING SYNTHETIC GEMS IN THE ELECTRIC FURNACE.

(Continued from page 297)

so far they have been the most successful in this class of work.

The first amongst these is the resistance furnace with electrodes of graphite with the crucible placed between the electrodes and directly into the flame. Another way of making the synthetic diamonds is to have the electrodes set in a flame of arc about 3,000 degrees Fahrenheit and the ingredients are dropped thru the flame in one batch and caught in a crucible set underneath, the crucible setting in water so that the molten mass is suddenly cooled, thus obtaining the necessary application of extreme heat and rapid cooling with the attendant and much desired pressure.

Lately Dr. Aisen's son has been the discoverer and has actually made artistic diamonds that bid fair to rival the genuine. The results have been the crowning effort of many years of thought and experiment and investigation. The method of procedure is somewhat along the following order:

1. In a crucible set in the electric furnace is placed iron of the best grade which is
super-heated until in a molten state. Then a pure grade of carbon is added and allowed to combine with the iron; when brought up to the desired degree the crucible containing the highly heated mass is plunged into cold water. As carbon is absorbed less in cold iron than in super-heated iron the action of the cooling of the mass serves to throw out the excess of carbon from the mixture. This carries, of course, some of the iron with it which forms around the edges of the crucible in the shape of diamond crystals. This is perhaps one of the greatest of all accomplishments in this field.

A very interesting procedure is the actual making of a synthetic jewel and the author had the good fortune to see the operation. One of the accompanying photos shows Dr. Aisen watching the slow process of the making of a precious stone as it grows gradually before the eyes. It is necessary to wear heavy goggles—dark ones of course—as the glare from the arc is very binding. The component elements are contained in the cup at the top of the arc and every three or four seconds it receives automatically a slight tap which allows a very minute quantity to drop from the hollow electrode and onto the stone that is in the process of making. The stone itself is perched on top of the lower electrode and the tapping process is controlled by a motor-driven arm.

In another view we see the bank of electric furnaces wherein the elements are placed in a crucible and then heated to the desired degree where they are "set" to cool in the furnaces gradually. When cool the mass is removed and the solid chunk of glass, for that is what it resembles, is broken and then comes the final processes of cutting, grinding and polishing. In all of the methods used, it is necessary to go thru the usual routine of cutting, grinding and polishing, the same as with natural stones as found in the rough.

Numerous methods have been employed in the artificial manufacture of precious gems, which apparently sound very simple as explained here, but one must not forget that many years of patient laboratory research were first necessary, to mention the study of numerical scientists who have devoted their lives in the search for Dame Nature's secrets. So that it is indeed wonderful as one always considers these beautiful man-made jewels, the product of the electrical furnace, the great stride made in the advance of the chemist's art.

ELECTRICAL EXPERIMENTER

Big Money in Electricity

The electrical industries offer wonderful opportunities to boys and girls for fitting for Electric License exams, which carry with them the pressing for the high paying position of Engineer, and the promise of wider opportunities for advancement. Thus a young man or woman, who is ambitious and willing to work, can get a start in this field of work with a high probability of success. The salaries paid to young men in the field of Electricity are increasing rapidly, and the best of all, the work is fascinating.

The discovery and development of new lines of work (such as telephone and telegraph) promise to attract many young men to the field of Electricity, and to make it a source of income for those who are not yet in the field. Thousands of young men have already won success in the field of Electricity, and there are many who will be able to support themselves and their families.

There's big money in Electricity. Get it by marking and mailing the Coupon today.

Just what you need to know to succeed in ELECTRICITY

EVERY electrician, every mechanic should know about these wonderfully helpful instructive books, which give in plain words a complete working knowledge of electrical engineering in all its phases.

You run into some new problem almost every day. The information you need to help you in your every day work is in

HAWKINS ELECTRICAL GUIDES

These books place electricity at your finger ends. They cover every imaginable subject, principle, theory, problem, and way of doing things electrically. Every subject is indexed so that you can turn right to it. They are a study course and a reference guide in one, written in plain everyday language—no wasted words—only what you need to know—check full of up-to-the-minute electrical knowledge.

The guides are a complete course in electrical engineering. They will help you in every detail of the day's electrical work. You can't ask an electrical question that Hawkins Guides can't answer.

Pocket-Size Flexible Covers

The books are small enough to slip into your coat pocket—handsomely bound in flexible black covers.

You can carry each volume with you until you need to refer to it. There are 942 pages, 2,355 illustrations, and 4,799 illustrations. Once you see these books and put them into actual use you will never again want to be without them. Try it at our expense.

SEND NO MONEY

It will cost you nothing to receive these books—to look them over—ask all the questions you can think of—use them in your work—study them—pick up some information that will increase your earning ability. We will ship you the entire set of 10 volumes returnable FREE.

This is a test of our confidence in the guides. The gold does not object to being tested. Keep them for over 30 days and if you do not decide that you can't get along without them, return them to us and we will refund your money in full.

Please send your order with this coupon to THEO. AUDE & CO., 72 Fifth Avenue, New York, N. Y. or your local Hawkins Guide dealer.

READ THIS PARTIAL LIST OF CONTENTS

No. 1 Contains 418 pages, 438 illustrations. Electrical signs and symbols—static and current electricity—primary cells—conductors and insulators—ultramicro- and conductivity—magnetism—induction coils—dynamos principles elaine of dynamos—motors—lightning—valve—armature brushes, etc.

No. 2 Contains 418 pages, 394 illustrations. Motor principles—armature reaction—motor starting—calculating-brakes—harness—connection and installation of dials and meters—galvanometers—standard cells—current measurement—resistance measurement—voltimeters—wattmeters—hour meters—operation of dynamo—operation of motors, etc.

No. 3 Contains 380 pages, 623 illustrations. Distribution systems—insulators—pole lines—lighting—中小型—tables—insulators—deaths—bulb—lighting protection—resistors—streaks—battery systems, etc.

No. 4 Contains 375 pages, 577 illustrations. Alternating current principles—alternating current diagrams—the power factor—alternating current—fulfilling—alternator—generator—alternators—connections—windows, etc.

No. 5 Contains 350 pages 614 illustrations. A.C. Motors—alternators and induction motor principles—A.C. commutators—new alternating current theories, transformer—construction, connections, tests—converters, etc.

No. 7 Contains 315 pages, 379 illustrations. Alternating current—wiring power stations—transformers—mainframe—repair—alarms, etc.

No. 8 Contains 325 pages, 438 illustrations. Telegraph systems—electrical systems—electric lights—power—current—telephones—electric—phones—telephone systems, etc.

No. 9 Contains 322 pages, 477 illustrations. Railway—electric locomotives—lighting—fender car operation—miscellaneous applications—wiring systems—engine locomotive—three-phase—lighting—starting and fielding systems, electric vehicles, etc.

No. 10 Contains 130 pages, 500 illustrations. Transformers—pumps—air compressors—electric heating—electric wells—motors—electric pumps—bi—electric plating—electric therapeutics—30 cents, etc.

Also a complete 125-page ready reference guide to the complete library. This Index has been planned to render easily accessible all the vital information contained in the 10 electrical books. There are over 13,000 examples in it. Use it within seven days and return it if you do not find it a most valuable aid.

THOUSANDS FIND THIS BOOK INVALUABLE

Please submit me for examination. If it's not for me I will return it to you for $1.00 within seven days and we'll settle it then.

Please sign your name if you wish to keep these books.

THO.

P.S. If books are received in good condition within thirty days after using them, you can return them to us for $1.00 each month until paid for.

Amazing Opportunities in the AIRPLANE INDUSTRY

Never before have ambitious men had such a glorious chance as is offered today in this wonderful new industry. The war news only proves that the Airplane has come to stay—that thousands and hundreds of thousands of airplanes will be demanded for commercial uses when peace returns.

Meanwhile an army of trained men must be found to man the new aeroplane factories that are now being built everywhere. This makes the big chance for you—a chance of a lifetime. Enroll NOW for our complete Course of training in Practical Aeronautics and the Science of Aviation, and prepare yourself in a few short months to double or treble your present salary.

We Teach You by Mail
In Your Spare Time at Home

Our new, scientific Course has the endorsement of airplane manufacturers, aeronautical experts, aviators and leading aero clubs. Every Lesson, Lecture, Blue Print and Bulletin is self-explanatory. You can't fail to learn. No book study. No schooling required. Lessons are written in non-technical, easy-to-understand language. You'll not have the slightest difficulty in mastering them. The Course is absolutely authoritative and right down to the minute in every respect. Covers the entire field of Practical Aeronautics and Science of Aviation in a thorough, practical manner. Under our expert direction, you get just the kind of practical training you must have in order to succeed in this wonderful industry.

Special Offer NOW
SEND THIS COUPON TODAY

It is our duty to help in every possible way to supply the urgent need for graduates of this great school. We have facilities for teaching a few more students and to secure them quickly we are making a remarkable Special Offer which will be withdrawn without notice. Write today—or send the coupon—for full particulars. Don't risk delay. Do it now.

AMERICAN SCHOOL OF AVIATION
431 S. Dearborn Street,
Dept. 7449, Chicago, Ill.

Prepare for one of these positions

Aeronautical Instructor $150 to $200 per week.
Aeronautical Engineer $100 to $300 per week.
Aeronautical Contractor
Enormous profits.
Aeroplane Mechanic
$50 to $75 per week.
Aeroplane Mechanic $40 to $60 per week.
Aeroplane Mechanic
$50 to $75 per week.
Aeroplane Mechanic
$40 to $60 per week.
Aeroplane Mechanic
$5000 per year and up.
Aeroplane Mechanic
$40 to $85 per week.
Aeroplane Mechanic
$75 to $200 per week.

This is the Electrical Age, and this wonderful new profession is calling you. The demand for expert Electricians is greater every year and the salaries higher. Electricity is truly the greatest motive power in the world, to-day, and now is the time to enter this profession.

YOU CAN DO THIS

AFTER HOME STUDY

$36.00 TO $100.00 A WEEK

You can earn $36 to $100 a week and more as an Expert Electrician. If you have a common school education I can train you in a few months at home. Big lighting and power companies, municipalities, and manufacturers are always seeking trained men to handle their Electrical problems.

SPECIAL OFFER: Owing to the big demand for trained Electricians in the Government Service I am making a wonderful offer for those who enroll during October.

I Guarantee Satisfaction

Every student receives our Sealed Guarantee Bond, which guarantees to return every penny of his money if he is not entirely satisfied. No other school has made this wonderful offer, but I know the success I have brought to hundreds of my students, and I know what I can do for any ambitious young man who will give me a little of his spare time each day.

FREE ELECTRICAL OUTFIT

MAIL THIS COUPON

CHIEF ENGINEER, L. L. Cooke, Chicago Engineering Works.
Dept. 20, 441 Cass St., Chicago, Illinois.

Without obligation on my part kindly send at once, fully prepaid, particulars of your complete Practical Home Study Course in Electricity.

For the next 30 days I am giving each student an Outfit of Electrical Testing Instruments, Tools, Electrical materials, and Motor absolutely Free. My instruction is by practical methods and this outfit is used in working out the lessons. Practical training with the theory makes perfect. I am Chief Engineer of the Chicago Engineering Works, and I can give you the training that will land the big jobs and hold them.

This is the only Correspondence School in America that has fully equipped Electrical Shops where students may come for special instruction.

If you are in real earnest I want to send you my Book—"How to Become an Electrical Expert." It's free. No matter how many other schools you write to I want you to have my book—It's different because it's practical—Write today.

CHIEF ENGINEER L. L. COOKE
CHICAGO ENGINEERING WORKS
Dept. 20 - 441 CASS STREET, CHICAGO, ILL.
Taught By A Practical Man
Prepare for the Future Now

When the war is won and over, thousands of unskilled men will be competing for a livelihood. Then more than now or in the past will the trained man dominate the situation while the man untrained will find his way made still harder by the preference naturally given to the returned warriors of no greater ability.

Now is the Young Man’s Opportunity

Prepare yourself to take your place among those who have made good. No matter what your present work or position, there is an open road to betterment.

Electricity is the Royal Road to Success

There is no industry today in which electricity does not bear an important part, either in the product or in connection with the manufacture. This calls for a constantly increasing army of skilled electrical workers who are invariably among the best paid men in the factory.

The Government Recognizes the Value of Trained Men

Recognizing the value of the skilled workman and desirous of giving young men every opportunity to become so trained, the government is as far as possible omitting young men of 18 and 19, even though they are within the draft age, who are endeavoring to fit themselves for positions of value to themselves and the country, and on the contrary have announced that they will call immediately students in technical schools and colleges who do not keep up with their classes.

We Make You Ready

Our course of instruction in Applied Electricity prepares you for success in peace and war. No matter what your previous training, if you are able to read and understand ordinary English we teach you the fundamental details of electricity including the building, operation and repair of motors, dynamos, controllers, batteries, and many other elements of electrical apparatus and equipment.

One Payment Covers Everything

We offer no free equipment or other misleading inducements. A moment’s consideration will show you that no man can give anything worth anything for nothing. If we misled you in one case, we probably would in others. We DO include with our course of instructions, without extra cost, tools, experimental material and apparatus, electro magnets, motors, electrical instruments, batteries and drafting outfits sufficient to enable you to do practical work in building, testing and operation.

Instructions by a Practical Man

Every student is under the constant supervision of Superintendent Yorke Burgess, a thoroughly practical consulting engineer who has had years of successful experience in Electrical Engineering and teaching by correspondence and personal instruction. Every student is taught as an individual with careful attention to his personal characteristics and ability, enabling him to proceed as fast as his grasp of details will permit and no student is railroaded through simply to complete his training.

We Have Made Good

Hundreds of students taught by Mr. Burgess are now occupying high-salaried positions of trust and responsibility. Many of these have of their own accord written us stating their success and recommending our course of instruction to others who may aspire to do likewise. Space forbids publishing these letters here, but we will be glad to submit certified copies to any prospective student who may be interested. We are proud of our record and their success may easily be yours. Write today.

Let Us Tell You How To Make a Big Success in CHIROPRACTIC

Advanced Science of Spinal Adjustment

Mail the coupon below, right now—today—and let us tell you all about the remarkable opportunities there are for ambitious men and women in this great, new profession of Chiropractic. You are, of course, aware that drugless healing is steadily advancing in public favor. Chiropractic has come to the front so rapidly during the past few years that it is today recognized as the most advanced, most scientific, and most successful of drugless healing methods. It is calling to its ranks men and women from every walk of life—and there is abundant evidence that they are making good in a big way in this new and uncharted field.

Mail the coupon and we will send you full information—tell you how there is a splendid chance for you to build a successful career as a Doctor of Chiropractic.

$3,000 To $5,000 a Year

There are many instances of Chiropractors earning from $3,000 to $5,000 a year. Some upwards of $10,000. Dr. M. D. Moore, of Kentucky, reports an income of $9,000 a year. Dr. L. H. Roche, New Jersey, $8,000; Dr. Hanna, of Florida, over $5,000 yearly. The success of Chiropractors in many cases has come so quickly as to be almost startling—almost like the accidental discovery of a gold mine. And yet, it is to be wondered at when you consider the scientific accuracy of Chiropractic methods, the really remarkable results of a beneficial character in the treatment of both acute and chronic cases that have been affected through these methods, the rapid increase in the number of people who have a decided preference for Chiropractic over any other treatment for their bodily ills and the comparatively few Chiropractors that are now in the field.

Your Opportunity

If others have achieved such remarkable successes is there any reason why you should not do as well or even better?

Why not get out of the rut and qualify now for this splendid profession that offers such remarkable possibilities for making your profession prosperous and independent? No matter where you live, if you are ambitious to make money, increase your social standing and be "somebody" to your neighbors, our course in Chiropractic will point the way for the attainment of your ambition. Never has there been a more opportune time than now, for never has the demand for competent Doctors of Chiropractic been so great as it is today.

SEND the coupon today. Don't delay. Do not think that your chances for building a successful career are less than others who are succeeding in the practice of this great profession. Just let us give you all the facts—then judge for yourself. Mail coupon or write today.

THE WAR MICROBE

By H. Gernsback

If we go back to the dawn of the human race we find that at the beginning the population of the earth was very small. It took literally hundreds and thousands of years before a million human beings were actually living at the same time on this globe. Many men had enemies who preyed on his existence and made life almost unendurable. Only very gradually did the race multiply. After man had conquered the more savage animals, new enemies beset him to keep the race from increasing too rapidly. Man's arch-enemy was, and still is, hunger. As long as he dwelt in the forest, primordial man had sufficient meat, which he obtained by killing animals, and being well fed, his health was good. But as agricultural man multiplied and kept on multiplying, there was soon not enough to eat and he began to starve much and often. This weakened his body considerably and a new enemy sprang up to slay him by the million—disease.

This was Nature's inexorable method to propagate a healthy race, for only by slaying myriads of human beings, for whom there was nothing to eat, could the race be perpetuated.

The human race had and still has to contend with many forms of disease, whether it be pestilence, cholera, tuberculosis or war. All of these diseases are working for Nature to keep up her “average,” i.e., the proportion of food to human beings. Let there be a food shortage for only a few years, and the population of the districts so affected will be materially reduced. Often, too, the thus reduced and starving nation becomes diseased with war and falls upon the richer nation, which by high living can afford not a weak resistance as a rule and succumbs. Thus for a time a balance between the two nations is re-established by Nature.

But well-nourished man is not always immune from disease, as is well known. He may succumb to the cholera germ as well as to the war germ, strictly in accordance with Nature's farseeing plan.

Thus, nations who have enough to eat for the time being and who consequently may be inoculated with the war microbe, as has happened so many times in history and as has occurred to the Huns in 1914. Here, too, we see Nature working out her “averages.” Side by side were France and Germany, each country of about the same area. But in Germany there were 66 million human beings, in France only about 39 million. Nature in her omniscient way to bring about a “balance” inoculated the German with the war disease, and we now witness the result where Germany is losing from three to five males, to every French male, this for the reason that the French at the outbreak of the war summoned her Allies who, now greatly outnumbering the Huns, slay them, thus reducing their numbers, thereby inadvertently executing Nature's decree. Exactly the same thing happens in every human nation, whether it be in the Middle Ages, where, in order to keep up “averages” between bees and food, the bees, after each swarming season is fall upon the males, the greater part of them being ruthlessly massacred by the workers, as in the dread of their consuming too much of the common store.

The human race has conquered many diseases and it will isolate the war microbe in time. But before that happens Nature will see to it that the non-food producing, prepondering city population is reduced in favor of the country population, so that there will be enough food for the rapidly increasing human race.

If we think of war as a disease, which finds its origin in hunger, and treat it as such, we will abolish it that much sooner.

H. GERNSBACK

The ELECTRICAL EXPERIMENTER is published on the 15th of each month at 233 Fulton Street, New York. There are 12 numbers per year. Subscription price is $1.50 a year in U. S. and possessions. Canada and foreign countries, $2.00 a year. (U. S. coins as well as U. S. stamps accepted as foreign coined or stamps. Single copies, 15 cents each. A sample copy will be sent on request, check and money orders should be drawn to order of EXPERIMENTER PUBLISHING CO., INC. If you change your address notify us promptly. In order that copies may not be delayed, lost, A postpaid wrapper and discontinue expiration. No copies sent after expiration.

The ELECTRICAL EXPERIMENTER is for sale at all newsstands in the United States and Canada; also at B. S. and 37 Avenue de l’Opera, Paris.
'LEARN BY DOING

The Only Way to Learn Electricity

The only way you can become an expert is by doing the very work under competent instructors, which you will be called upon to do later on. In other words, learn by doing. That is the method of the New York Electrical School.

Five minutes of actual practice properly directed is worth more to a man than years and years of book study. Indeed, Actual Practice is the only training of value, and graduates of New York Electrical School have proved themselves to be the only men that are fully qualified to satisfy EVERY demand of the Electrical Profession.

At this "Learn by Doing" School a man acquires the art of Electrical Drafting; the best business method and experience in Electrical Contracting, together with the skill to install, operate and maintain all systems for producing, transmitting and using electricity. A school for Old and Young. Individual instruction.

No previous knowledge of electricity, mechanics or mathematics is necessary to take this electrical course. You can begin the course now and by steady application prepare yourself in a short time. You will be taught by practical electrical experts with actual apparatus, under actual conditions. 5,000 of our students are today successful electricians. Come in and read their enthusiastic letters. Let us explain this course to you in person. If you can't call, send now for 64-page book—it's FREE to you.

O UR NEW 400,000 C.P. AEROPLANE FLARES

For carrying out night operations under war-time conditions the Teutons, as well as the Allied air forces have often resorted to the use of "flares" as they are called. These are usually dropped from airplanes or dirigible balloons, and, suspended from parachutes, they give an intense illumination over considerable areas.

Uncle Sam's ordinance experts have something new to spring on the "All Highest" shortly—a new "flare" light that will give 400,000 candle-power, and light up a circular area one and one-half miles in diameter!

An airplane flare, with a brilliancy equaling that of 400,000 candles has been perfected, says our official report from Washington. When hanging from its parachute over a German munition plant it lights up an area so brightly that an airman, thousands of feet in the air, can select any building he is directed to make a target for his aerial bomb, and, it may be added, American aviators are becoming so expert in bombing that they can usually hit the target at which they shoot.

In every European city within the zone of aerial raiding operations, the rule is rigidly enforced against the burning of lights in any building that might possibly be used as a target. Therefore, the airman must be able to supply his own means of locating the object of this attack.

When orders are received to bomb, say a particular railroad center, the aviator proceeds very much in the same manner.
Electrical

The drops, to "Hand sufficient" lifted H in idle power, section, terrain powerful.

"Flare" just what a night "Flare" can do is readily imagined by looking at this photo of a British "Heavy" and its crew lighted up by a German Star Shell. Note the camouflage on the barrel and also the captured "Boches" working at the left.

"Flare" is equal to that of a battery of from 150 to 1,750 street arc lamps, or of from 15,000 to 17,500 ordinary incandescent lamp bulbs such as are used in the home!

As soon as the flare gets into operation, a huge parachute made of the best quality of silk opens and holds the brilliant light in suspension in the air for a sufficient time to allow the aviator to select his objective or target. Having located the factory, railroad depot, ammunition dump, hangars, munition plant, or whatever the target may be, the aviator drops the bomb and proceeds on his way. His aim is certain to be most deadly with such perfect illumination as is provided by this newly perfected "flare" light.

The height at which an aviator flies when attacking depends, of course, on surrounding conditions. If the enemy is aware of his presence and is preparing for attack, he must keep up and out of range of anti-aircraft guns. An idea of the effective light thrown on the ground by this flare may be gained from the fact that, when suspended at a height of from 1,500 to 2,000 feet, it will clearly light a circular area one and one-half miles in diameter.

Belgian use new electric trench mortar.

A new development in mortars on the Belgian frontier, makes use of electricity as the prime agent of operation. Its purpose is to clear the barbed wire entanglements in the line of advance. A very novel method of timing the explosion is employed.

It can be used in close quarters where there is not ample time for the shell to enter the mortar, by grasping the shell by the wire and swinging it over the head, then throwing it into the enemy trench. When put to the latter use it functions the same as when fired from the trench mortar. The pin is pulled when the shell is lifted and swung by the wire; the action is explained by the accompanying diagram.

The shell shown here is one of the units that is placed into a metallic container and fired with its rear end forward. It is aimed

Just What a Night "Flare" Can Do Is Readily Imagined by Looking at This Photo of a British "Heavy" and Its Crew Lighted Up by a German Star Shell. Note the Camouflage on the Barrel and Also the Captured "Boches" Working at the Left.

The Belgian Electric Trench Bomb Used for Destroying Barbed Wire Fences, Etc. It Can Also Be Used as a "Hand Grenade."
How "Blimps" and Telephone Aid Artillery

THE accompanying illustration shows a Telephone Exchange Lorry of the British Royal Air Force in communication with a dirigible balloon. Many of these balloons are used for observation purposes and the observer has to be ready for almost any emergency, as he is in constant danger of being attacked by enemy shell fire or aircraft. Should the observer be attacked he descends by means of a parachute. The observer is connected to this Lorry by telephone by which he can communicate with headquarters.

The balloons used for the purpose are of several types, some being of the simple gas-filled "blimp" variety, held by a steel cable from the upper end of which they swing about in the breeze, while others are of the dirigible gas-filled design here illustrated. The dirigible carries a gasoline engine power plant and propeller at the front of the nacelle or crew's basket, by which means it can move about in the air and maintain any desired position in a considerable wind. The dirigible balloon does not have to depend on an anchoring cable and winch to pull it down, but can ascend and descend by its own power, suitable rudders largest electrolytic gas generating plants existant. These generators have a series of large cells fitted with oppositely charged plates which are immersed in water. The passage of the electric current thru the water decomposes it into its constituents—hydrogen and oxygen gas (H₂O). The hydrogen gas is led off thru suitable passageways and pipes and fed into the balloons in their "beds." There are fifteen balloons now in use at Ft. Omaha.

This balloon instruction camp, one of the most efficient and best equipped, has recently installed besides the electrolytic gas generator, the first silicon plant in this country. In this new form of balloon gas plant hydrogen is made from caustic soda and ferro silicon. As many as twenty-two steel bottles, each with a capacity of 2,000 cubic feet, under compression of 200 pounds to the square inch, are filled in a single day. In actual war service on the battle-fields of Europe, powerful motor lorries, each loaded with several dozen of these gas bottles are dispatched to the various balloon depots as required. Sometimes the bottles of several trucks are all connected up to a common pipe leading to the balloon "beds."

To be a balloon observation officer is a real distinction, for besides being fully at the mercy of enemy aeroplanes, who may pump him full of bullets before he can down the attacker with his rifle or Hotchkiss gun, he must be an accomplished map reader and map draftsman—not to mention the knowledge of spotting shell hits instantly, radio operating, telephony and telegraphy, balloon rigging and maneuvers, weather forecasting, etc. When the balloonist leaves the U. S. Army school he must know all these things and many more, and be able to note and record shell hits at a distance of four miles.

An electrically operated vacuum cleaner for the teeth has been patented. Let's introduce them to our after dinner speakers!
The Artillery "Barrage"—How It Works

By H. WINFIELD SECOR

By means of the artillery barrage as it is usually employed, three major operations are carried out in a short space of time, once the hundreds of guns have been lined up almost hub to hub for the purpose, and these are as follows:—First, either a portion or all of the guns start firing on the second in a "searching barrage" extending over a considerable stretch of the enemy's ground behind his trenches for the purpose of cutting off his communications, preventing the bringing up of supplies, and reinforcements of troops. Secondly, and meanwhile some of the guns keep up a "standing barrage" on the enemy first and second line trenches. It is interesting to note that the watches used by the infantry officers in the Allied trenches, as well as those used by the artillery officers, are of the split-second type, because while the troops are to advance behind a barrage, perfect coordination must exist between the artillery and the infantry—in order that when the troops advance, the curtain of explosive shell shall advance at a certain prearranged distance ahead of the wave or waves of infantry.

The "searching barrage" is set up several hours before the time that the infantry is ordered to advance, after the enemy trenches, filling the landscape for several miles with shell holes and craters, and smashing his wagon and auto supply trains, putting an end to the enemy's possible communications. The thunderous detonation of bombs, shells, and gas shell raises the devil with the enemy, not to mention his casualties and the destruction of enemy guns, ammunition, and ammunition dumps.

Thus far we have the preliminary "searching barrage" and the "standing barrage", which latter is kept firing on the enemy's front line trenches. We then come to the critical moment when our troops are to go "over the top", and this exact time is, of course, very critical. On this is based the entire strategy of the allied artillery and infantry officers concerned. Part of the artillery barrage batteries, just prior to the moment when the infantry is scheduled to go "over the top", is ordered to start the third operation, called the "creeping barrage", which is a barrage, b e h i n d which the "dough-boys" are to advance behind the enemy trenches. The accompanying diagram of a creeping barrage, and the time-table shows how wonderful this operation actually is, especially when one stops to consider the several dozen different and highly diversified factors which enter into the firing of even a three-inch field gun. For who would believe that one could tell a hair as to just what pressure a certain charge of explosive in a cannon barrel will create, and how far it will throw the projectile? Then again we have such variables as the wind velocity, the humidity of the air, gun erosion or pitting due to wear, etc. Inverting once more to the "creeping barrage", and the troops' advance on the enemy trenches, we learn that the creeping curtain of shell-fire starts about twenty-five paces in front of the Allied trenches. In one minute the barr-
A Comprehensive Panorama of a Section of the Western Battle-front When the "Doughboys" Make an Advance Behind a "Creeping Barrage" or Curtain of Shell-fire. For Hours Previous the "Searching Barrage" Has Combed the Enemy Trenches and Supports to a Depth of Several Miles. It Has Taken Days and Weeks to Prepare the "Barrage"—But it is Worth It.
Movie Tricks Exposed

By W. EDOUARD HAEUSSLER

HOW often has it annoyed you, while lounging comfortably in your favorite motion picture theater, endeavoring to enjoy the latest photo-plays to be seated behind the pest who claimed to be on speaking terms with Francis X. Cushman and Mary Ford pick and who was forever "explaining" to his friends beside him how all of the mysteries and illusions of the movies were made and worked out in the studios. Did you ever stop to reason how they make an automobile race toward you and at the psychological moment when the auto appears to come crashing into the camera, forward movement as reverse motion. This method is also employed to produce the illusion of a man jumping from the third-story window of a building to the sidewalk and then back again, without any mechanical means or hoisting apparatus.

The various films showing an enormous speed of action are of the "Speedex" class. This novelty was first released to the public in a series of screen travelogues by Burton Holmes. In one of the films showing a steamship passing thru several canal locks, the time for the actual operation of which is figured in hours, is very rapidly portrayed on the screen in the course of a few minutes. This method also enables one to see the action of very slow and hardly perceptible motions, extending over a long period of time. In this particular type of subject, the moving of a five-story house can be cited. A freak film can be obtained by camera and one is not surprised to see a ship racing thru the water at an unbelievable rate of speed. This unique process is accomplished by taking the pictures at a reduced rate of speed, that is, less than 16 frames per second; and at successive intervals in the case of a subject, the completion of which may be a matter of weeks. When these films are projected on the screen at the normal rate of speed, they appear noticeably accelerated.

It is a peculiar fact that films photographed at a speed less than normal (16 pictures or frames per second) and projected at the normal speed show a very rapid motion. Likewise a film when exposed at a high rate of speed above normal attains a very slow action when projected.

The Ultra-cinematographic Film Camera is based on this latter principle. This type of film is exposed at the rate of 100 frames per second. When projected at normal speed, the photograph of an athlete jumping a hurdle is so slow in action, that every muscular movement can be analyzed, and exceptional detailed action giving the entire hurdle jump a floating appearance as tho the athlete actually had a pair of wings.

In Figure 5, is shown the chronological progression in the manufacture of a "movie" from the time that the camera first opens its shutter upon the scene until you are thrilled by the same scene at your favorite playhouse.

The second phase is the taking of ordinary photographs termed "Still". These photos are obtained during the taking of the scene at a signal from the director to stand still. The photo is then taken. In some instances after the scene has been filmed, the director calls for a reassembly of some crucial tableaux for a still picture. These "stills" are used for advertising purposes and are displayed in front of all Motion Picture theaters. A common belief
that one often hears expect is to the effect that these advertising placards are made by enlarging the small \( \frac{3}{4} \times 1 \) inch frames. This is, of course, utterly impossible as a distinct and sharp outline could not be obtained were these small pictures to be enlarged to one of from four to five feet in size.

The developing of the exposed films is the third stage of the process. After the films have been developed they are placed on large reels and whirled rapidly until thoroughly dry, as illustrated by Fig. 1. Black objects when photographed, appear as white on the master or negative film; white likewise appears as black. This condition is transposed in the fourth step, that of printing or the making of positive films.

Some firms procure the positive films in a non-perforated state and make use of the machines shown in Fig. 2. These positive films are put by placing them upon the master film and exposing to a strong light. They are then fixe in a chemical bath so as to retain their images without any further treatment.

Figure 3 will give you an idea of the intricate and delicate machinery and instruments that are employed for this step. After the films have been printed, these positives are run thru the polishing machine. This is an important operation, as it removes all particles of dirt and dust from the celluloid side of the film. A photograph of this machine is shown in Fig. 4. "Matting" is the fifth and most tedious portion of filmic art. Under this heading all of the scenes are placed in proper sequence. This work is again checked under the heading of inspection. Here the film goes under the close scrutiny of a trained eye to pick out all mutilated sections, blurs, scratches and the operator cuts out faded, overexposed and blurred portions of the reel. The censor's review is the "anxious seal" of all films and if they are past upon, they are ready to be distributed to exhibitors throughout the various countries. The last phase is for you, Mr. and Mrs. Reader, to decide—that of the romance, acting as a Board of Critics. For it is according to how you "take to" the film that determines its future success or failure. Film producers are attempting to please all manner of tastes and are succeeding remarkably well. This is proven beyond a doubt by the crowds that frequent the innumerable photo-play houses and theaters.

There is still another and most interesting part of the Cinematograph Industry. These diagrams are a series of visual lectures on the screen portrayed by animated drawings produced by the Bray Studios. Mr. J. R. Bray is the originator and creator of animated drawings and cartoons, a strip of which is shown in Fig. 6. His previous wonderful gift to the Motion Picture. Followers of this distinct type of comedy has stood alone in its field. Its scope has been enlarged upon by Mr. Jacob F. Leventhal, an associate of Mr. Bray, by an ingenious adaptation of Mr. Bray's creation for scientific uses. It lends itself to an unlimited degree of adaptability and has been most successfully applied. The most noteworthy use in the scientific field to which this class of motion picture film has been put is to teach rapidly and efficaciously warfare to "Our Boys" by this new method. The moving picture is being widely used in the training of American pilots in England.

The young flying officers who are sent to the Armament School there to acquaint themselves with the use of airplane guns and gun gears find their three weeks' course a most interesting one, owing partly to the large share which the moving-picture machine plays in the instruction.

The pupil is not required to sit out a lengthy lecture and read aloud from the notes of an instructor. Instead, the various branches of gunnery training, such as the stripping and assembling of guns and the various points to be observed before, during, and after flying, are demonstrated by films, accompanied by concise explanations by competent officers.

There are numerous and interesting tricks employed by the various producers to attain certain desired results. Take as an example a feature representing "Satan." He suddenly vanishes amid a cloud of smoke. This disappearing phenomena when portrayed on the screen is awe-inspiring and remarkably well executed. During the production of this scene the disappearance is (Cont'd on page 408)
The Automatic Soldier

By H. Gernsback

A science advances, and as all sorts of infernos which have thrown into a modern war, the men in the front line trenches become less and less anxious to bear the full brunt of high explosive shells, liquid fire and what not. No matter how courageous a body of soldiers, their morale is bound to deteriorate considerably under a mustard gas attack, or under a modern barrage.

As has been so often demonstrated in this war, if the men in the first and second line trenches can be demoralized, the enemy as a rule can tear quite a gap into the lines, and make his assault in strength. If we could devise some sort of device who was bomb and shell proof and who did not mind either liquid fire or the most vicious kind of gas, our front line trenches would be very much more secure than they are now. It would be difficult to storm such trenches.

This is exactly what a Danish engineer has had in mind when he recently obtained patents on a device which he terms an "Automatic Soldier." Trials recently made with the device, in which soldiers are reported to have been eminently successful.

Our front cover as well as the accompanying illustration show in a clear manner the "soldier" briefly consists of a special double steel cylinder made of shell-proof Tungsten steel or the like. There is one stationary cylinder, and a second inner cylinder, the latter telescoping into the stationary one. The entire device is set into trenches as shown in our illustration, the inner cylinders taking the place of a human soldier. These automatons may be spaced from one to three yards apart, and the operation is as follows: As there are two cylinders—one, the outer, in the form of a can, and the inner one, in can-shape, too, but with a dome at the top, and a base at the bottom. The inner cylinder rises and falls down vertically and normally the dome is level with the surrounding land. When the 'soldier' goes into action, the inner cylinder rises eighteen inches, which brings it above the parapet of the trench. In other words, the automatic soldier normally is invisible, and can be seen when the inner cylinder rises. The guns as well as the entire mechanism are entirely controlled by wireless, operated from five or more miles at a distance. If the commander wishes to open battle with his automatons—he merely notifies his wireless control station, which immediately sends out impulses, and these in a well-known manner operate the automatic soldier.

The first impulse raises the inner cylinder above the trench. The second impulse pushes the machine guns thru the slots of the dome, while the third impulse moves the inner cylinder so as to direct the fire. The fourth impulse may set off the machine guns, each of which, according to its invention, may be far enough away to give it hundreds of rounds into any given direction.

Our front cover shows the disposition of the aerial wires which encircle the main steel cylinder. It goes without saying that the fire of the machine gun can be stopt by radio by sending out the correct impulses at any desired moment. The aerial observer flying over the trench lines containing the automatic soldiers sends back his wireless reports so that the fire of the automatics can be directed where it does the most good.

The action of the device is such that the instant the guns stop firing, the inner cylinder immediately sinks into the outer one, thus disappearing from view. It goes without saying that the device cannot only be used to pump bullets into the oncoming enemy, but they can be used as well for other purposes, such as to belch forth liquid fire or to let loose a gas attack as depicted in our cover illustration. Perhaps it would not be a bad idea to equip every automatic soldier with a gas tank, all of which will certainly tend to stop the most gallant as well as vicious attack of the enemy.

While machines of this kind seem very cumbersome, and perhaps not efficient, because it may be argued that they cannot think, nevertheless they would offer an extremely much more valuable than the average soldier. For one thing, the machine knows no morale—it never retreats. It is not affected by shell shock or musketry, and liquid fire has no effect upon it. It never surrenders and never turns traitor. In order to be overcome, the automatic must be destroyed by one, possibly only by exploding large quantities of T.N.T. against its sides. As long as the ammunition lasts no soldier would care to approach it, as he would never know when the wireless would set it off, which would immediately bring the automatic into action, no doubt killing the attacker.

It is difficult to see how ordinary infantry could overcome these automatons if planted three or four lines deep. Each trench line would thus be tremendously odds, and there is not a soldier living who would stand up under the withering fire of such automatons who know no fear.

A device of this kind, of course, not chimeric, but entirely within the realms of present day science, and we would be very much surprised, indeed, if the automatons would not make their appearance soon at strategical points along the front. Nor are they difficult or expensive in construction, each unit of the automatics does not necessarily cost more than five or six thousand dollars, which is but the price of a modern torpedo. The wireless apparatus does not take up much room, while the motors which drive the entire mechanism may be readily operated by a 24-volt storage battery placed at the bottom of the large cylinder. All the parts of the mechanism is readily worked by compressed air which can be replenished easily at night after the automatics have been in action during the day.

This is the case also of ammunition, gas or chemicals for liquid fire, all of which can be replenished during the night time by men walking up to the machine thru lateral trenches.

Of course if there was no action during the day, there would be no need for replenishing gas or chemicals.

It should also be understood that these automatons can be operated singly or in groups by means of electric cables buried into the trenches, if it is preferable to use this method instead of the not always so reliable wireless.

HISTORY OF THE RELAY WHEN "HUN" MET "YANK."

There is a curious fact connected with the history of the telegraph relay. It could not be patented in Germany, and therefore could not with safety be exposed. In 1846 two young Americans named Charles Robinson and Charles L. Chapin had gone there with Morse apparatus to try their fortunes in building lines. Wheatstone had a rival instrument which he offered to sell to the government, and the price was fixed.

Some time later, the American government threw open the contract to English manufacturers. These heeded the call, and built a line from London to the French border. The English line was finished the next year, and the American government then called upon the firm of Chapin and Robinson to build a line from Washington D.C. to the Chesapeake Bay. The line was built and the government was satisfied. The word spread that the apparatus was not very satisfactory.

Once in a while, the government would throw open contracts to private enterprise. That is just what happened when the government let a contract for a line from the Lake of the Woods to the Mississippi River. The government was satisfied with the work, and the line was ready for operation.

Perhaps it is not generally known, but the government had at this time a mixed motive in the introduction of electric telegraphy. It seems that the government was more interested in the apparatus than in the lines. It wanted to get the apparatus for its own use, and the government was not satisfied with what it could buy from the English manufacturers. The government decided to build the apparatus itself, and the result was the...
Locating Submarines by Reflection

Devices for locating or detecting the presence of submarines are in great demand nowadays, for once a war vessel or merchantman becomes apprised of the fact that he is face to face with a sub-sea fighter, the officer in charge will at once put himself on the qui vive. The gun crews can at once be summoned to quarters, and if the enemy is to be located at night, the searchlight can be caused to sweep the waters, and the vessel put on a zig-zag course, these precautions having saved many vessels from a disastrous finish as the press reports of such encounters have indicated in the past. Only recently there was a case where an English merchantman spotted the periscope of a submarine—in other words, he was at once apprised of the fact that he had to face two kinds of warfare, by torpedo and by gun fire. To show that it proved valuable for the skipper of this vessel to know what conditions he was up against, it can be said that the captain caused the vessel to pursue a zig-zag course, and shortly after starting this maneuver, the boat managed to just miss by a few yards a white-nosed German torpedo. Presently the submarine arose to the surface and started firing with her deck guns. The merchantman, however, had the best of the game, for being provided with guns both fore and aft, the U-boat was efficiently bombarded and after the twenty-sixth shot the sub-sea craft was rendered helpless, and according to the report of the merchantman’s commander, the U-boat was undoubtedly sunk.

All of which leads us to the invention here presented which comprises an optical submarine detector invented by Edward S. Jones, of Mobile, Ala. In the words of the inventor, “This invention relates to improvements in a scientific instrument for locating submarines, floating mines, and other objects of menace to navigation, within a certain radius about the ship. It consists primarily of a series of reflectors, cooperatively so arranged as to show upon a magnifying mirror the surface of the sea and objects thereon within a given radius, so that it may be observed from the look-out cage at the top of the mast, as the illustration herewith depicts, thus enabling the proper officers on board the vessel to be instantly warned of any danger so as to defend the ship if armed, and to escape if unarmèd.”

As the drawing shows in detail, the look-out cage is fitted with speaking tubes as well as telephones for maintaining constant communication with the bridge and officers’ quarters. In the form of the invention here illustrated, the reflecting mirror is concaved, and has its upper end broadened so as to reflect images on the surface of the water as indicated by the dotted lines on to the magnifying mirror, on which the officer looks. This magnifying mirror is preferably graduated by very fine lines running at right angles to each other, their purpose being to assist the observer in locating the distance the reflected image is from the ship. The farther away the submarine or mine happens to be, the smaller, of course, will its image appear on the magnifying mirror, and vice versa.

A powerful electric searchlight or series of searchlights are arranged above the optical locating device just described for use at night, and the searchlight compartment is arranged with suitable windows and shutters so that the one or more beams of light used can be swept over the water rapidly in any formation desired. The device is effective over 180 degrees of horizon.

Here's the Latest Anti-Submarine Invention. The Patentee of the Scheme Illustrated Proposes to Mount a Large Concaved Reflecting Mirror and a Magnifying Mirror at Some Elevated Point, as for Instance on the Mast of a Ship, and to Thus Pick Up By Reflection the Image of a U-Boat or Its Periscope. The Magnifying Mirror Is Ruled Off in Squares to Facilitate Measuring the U-Boat's Range and Direction.

GERMANS USING MEXICAN RADIO?

Activities of Germans or German-Americans from the United States across the Mexican Lower California border, where a wireless plant is located, are now under investigation by Government agents.

Reports indicate that for months groups of about fifty Germans, changing every week or ten days, have been found in Mexicali, a torrid little collection of baked shacks just across the border from Calexico, Cal.

The Germans, who were never known to visit the town before the war, now congregate at a store started recently by a German. This German is known to have been active in propaganda work in the United States before the war. The Germans have used the wireless station there, which is capable of communicating with Mexico City.

Government officials profess not to know how the Germans reached the town from the United States, since the railroad is carefully watched. It is suspected they cross the border at a number of points in sparsely settled communities.
An Electric Speed and Direction Indicator for Trans-Atlantic Planes

It is easy enough to read of making a Trans-Atlantic aeroplane flight, but when it comes down to actually making such a trip, no one but an experienced aviator, or one who has studied the subject very closely, can imagine just what this means. In the first place, the layman thinks mostly in terms of horse-power and wing surface, and he argues: Given sufficient of these two quantities and a good pilot, there should be no trouble at all to fly across the Atlantic Ocean at its greatest breadth, of say three thousand miles or more. But he forgets one thing, and that is, that it is almost impossible for an aviator, no matter how experienced or well traveled he may be, to steer a course across such a vast expanse of water as the Atlantic Ocean, for he cannot check his route by any familiar or well-known land-marks; and even when using the latest scientific apparatus, such as the Sperry Synchronized Drift Set, which utilizes the wave movement or a succession of movements to warn the aviator how his machine is being drifted or forced sidewise from the desired course, he would be at a loss to utilize such an instrument whenever the visibility happened to be low, and particularly when low-flying clouds or mists were encountered, which would cut off his view of the underlying water. The same problem would confront him during night flying, especially when the moon happened to be obscured.

The idea held by most of the aeronautical engineers who have discussed this idea in the technical press. As has been pointed out in several of the discussions concerning this method of indicating the direction of flight of an aeroplane and the mileage covered, there is the objection, albeit slight, that

(Continued on page 412)
Searchlights Mounted on Anti-Aircraft Cannon

The electric searchlight has been advantageously combined with many different forms of war machinery in the past few years of the great international calamity across the sea, but possibly one of the most unusual adaptations of the electric searchlight is that shown herewith, which illustrates how the English cannon employed for the defense of London against enemy aircraft, was fitted with a small searchlight in order to increase the rapidity and accuracy of fire. The anti-aircraft gun is mounted on a tall building or promontory, or else on a high powered motor truck so as to speed rapidly from place to place. Such a combination spells deadly accuracy of fire, as anyone who has experimented with the electric flashlight pistol will have found, for when the searchlight or flashlight beam was centered on the target, and the shell or bullet dispatched, it struck the center of the spot of light on the target; in the present case, it would strike in the center of the beam from the searchlight. It can readily be imagined with what rapidity the gunners can "spot", an enemy aeroplane or dirigible and bring it down.

McAdoo Would Electrify All Railroads

Director-General of Railroads McAdoo said recently on his return from a trip that his observation of the vast resources of water power during the two months he had been absent from Washington since the close of the last bond campaign, had impressed him with the idea of electrifying the railroads of the United States. If the Government were to continue the administration of the railroads of the country for any prolonged period, he said, he would be in favor of resorting to the use of electricity just as far as it could be practically employed.

Director General McAdoo said that for the present nothing could be done toward substituting water-power for coal-produced steam, but it might come as a plain matter of necessity while this war was on.

U-BOAT IN SPANISH PORT DIRECTS RAIDS BY RADIO

Investigation has disclosed that the German submarine U-56, recently arrived at Santander, Spain, under its own power, had been in communication with other U-boats at sea.

Commander Reisser of the U-boat, repeatedly was seen signaling toward the sea, while the Spanish government intercepted wireless messages from the U-56 after a French steamer was sunk and its crew killed by a submarine.

It is quite obvious that the U-56 was sent to Santander to organize the destruction of Allied and Spanish shipping from a favorable spot, it is believed.

French View of Electricity in Modern War

The important part played by electricity in the modern war is set forth in an entire number recently given over to the subject by the leading French magazine, Je Sauve Ton. Trench warfare has imposed the use of the telephone for the transmission of orders, for reports and for communications of all kinds. In order, however, that it should be the ideal agent of communication, there are certain features attending the use of electricity in this connection not necessary in times of peace.

Communication must be secret, and the wires must be placed so that they cannot be destroyed by shot or shell. In the first days of the war the Boches quite successfully tapped the French wires. Their listening posts were discovered, and the telephone officer attached to each regiment has so disposed of wires and currents that secrecy is now assured.

A means of making use of the electric magnet under water has been devised in Japan, and it promises to be of great assistance in locating sunken vessels, to recover which salvage operations on a big scale are expected after the war.

ARC-WELDING SAVES MONEY

Arc-welding by electricity has been brought prominently before the public through the fact that it was used to restore the broken engine castings of the interned German steamships. When breaking these castings the much learned Englishmen thought they could not be repaired, and that it would require a year or more to replace them. However, even before the
WHILE all of the vast resources of the country are being combed and recomb by the various experts connected with the National Gov-

ernment in order to produce the greatest output of war materials at the most economical cost, and also to conserve the
great resources of the nation to the highest possible degree, a stupendous amount of power is daily and hourly going to waste, viz., that hydro-electric power which is not being developed as yet.
The rivers, lakes and waterfalls of the country represent a source of energy suf-
ficient to care for a large proportion of all the needs required for our industrial and social life, if they could be harnessed and applied to our requirements in an efficient manner; some of these waterpower develop-
ments, however, would prove uneconomical owing to the high initial cost in harnessing them to our needs.

Waterpower is not, however, confined to rivers, lakes and waterfalls, but there is constantly millions of horse-
power going to waste in the action of the ocean waves along our sea-coasts of which we have several thousand miles on the Atlantic and Pacific seaboards. With the idea in mind of utilizing the gigantic power inherent in this constant wave motion which perpetually rolls up on our beaches day after day, year in and year out, a Yankee inventor, Mr. E. T. Stodder of New Rochelle, N. Y., has given a large amount of his time to the study of wave motion and devices inten-
tended to turn into industrial use the great power which they possess. His invention is shown in the illustrations here-
with.

The larger view shows how Mr. Stodder's wave motor would be installed in a manner which much resembles one of the large steel piers to be found at any of our seashore resorts.

The basic idea of this wave motor involves the utilization of the powerful lifting force exerted by the waves as they rise and fall, and to this end the inventor proposes the used of large steel float members, each float in a commercial sized machine to measure about eighty feet square, thus giving an area on which the wave can exert a lifting action, of 6,400 square feet, while a num-
ber of these floats can be placed along the pier as our illustration shows. At each end of these steel float members, which are air-tight of course, there are two steel cables which lead upward to specially devised air compressors, so that no matter in which direction the float rises or falls, efficient work is performed by each and every move-
ment of the float.

All of the comprest air generators connected with the cables from the floats, are connected with a main pipe line, and this in turn feeds a comprest air motor connected with an electric dynamo. The dy-
namo produces electrical energy which can be fed into storage batteries, and also to the wires supplying electric lights, etc. The smaller illustration shows a perfect model of this unique wave power plant built by Mr. Stodder, and in which the float member is shown suspended by the upper and lower end cables aforementioned, each cable be-

The Latest Idea in Wave Motors—it comprises an extended series of buoyant tanks or "floats," each float rising and falling with the waves and serving to compress air. The comprest air drives a pneumatic motor connected to a dynamo, thus producing free electric-

ity from the ocean waves.

Model of New Wave Motor Built by its Inventor, and Demonstrating How Each "Float" Operates Alternately Eight Air Compressors, Thus Utilizing Effectively Every Motion of the "Float."
This Car Carries a Complete "Power House"

What is believed to be the most powerful self-propelled car yet built in the United States has been placed in service on the lines of the Nashville, Chattanooga & St. Louis Railroad.

Built by a New York locomotive concern, it has a 150-horsepower oil engine of the standard four-cycle eight cylinder marine type direct connected to a 100 K. W. differential compound wound 250-volt direct-current generator running at a constant speed of 1,000 r.p.m.

A storage battery having a rated capacity of 483 ampere hours at a five-hour rate is also installed, the combination of generator and storage battery providing ample reserve power for peak loads. The car is propelled by electric motors attached to the axles, thus providing the most flexible control possible. It is the same principle as that used in the new electric-drive warships, which have shown the quickest and most flexible control of any arrangement hitherto utilized. The engine burns either kerosene or fuel oil. The oil passes from the storage tank to a gas generator placed in the muffler of the exhaust. From the generator the gas passes directly to the cylinders of the engine, being mixed with air in the proportion of one part of gas to six of air.

The storage battery is suspended underneath the car body and operates in parallel with the generator, which is so constructed that the voltage automatically coincides with that of the battery. The generator will deliver current up to its capacity, while at the same time it works in unison with the storage battery which delivers any excess of current the load may require. The battery will deliver 400-horsepower for five minutes, 210-horsepower for fifteen minutes, 93-horsepower for one hour, and 30-horsepower for five hours. This power is in addition to the 150-horsepower developed by the engine. Thus the car has an abundance of power for acceleration or while ascending heavy grades. With this arrangement the engine works at nearly full load at all times, and the efficiency is therefore a maximum. All the power required above the capacity of the engine is supplied by the battery, and all power generated by the engine and not required to drive the car is employed to charge the battery, which furnishes a convenient source of energy for starting the engine, lighting the car, operating the auxiliaries and in case of emergency driving the car itself.

According to an Italian scientist's figures, a square mile of the earth's surface in six hours of sunshine receives heat equivalent to the combustion of more than 2,000 tons of coal. And we scientific barbarians can't as yet harness 1/1,000 of one per cent. of it. Some day we may learn how.

The Latest Type of Gas-Electric Car. It is Driven by Electric Motors Which Derive Their Power from an Oil Engine. Electric Drives are Used to Care for Extra Demands On Ascending Grades, Etc. No Trolley is Required as the Power Plant is Self-Contained. Electric Drive is Used to Maintain Even Engine Speed and Great Flexibility of Drive.

A Remarkably Fast Electric Blue-Printing Machine. It Prints, Washes and Dries the Prints—All in One Continuous Operation. One of These Machines Has a Capacity of Five to Six Linear Feet of Finished Blue-Print Per Minute.

ELECTRIC RIVETERS WORK RAPIDLY.

Electric riveting machines are now being used in the erection of the huge steel work. The machines hammer home the rivets in short order, and by their use some good speed is being made in the work.

An electric heater has been invented to prevent moisture collecting on an automobile wind shield.

MODERN ROTARY ELECTRIC BLUE-PRINTERS.

By Frank C. Perkins

The accompanying illustration shows a rapid, continuous electric blue-printing machine in operation in connection with an automatic washing and drying machine, as developed at Chicago, Ill., and showing the course of paper thru the machine.

It is pointed out that in these days of business activity every engineering department feels the necessity of having its own up-to-date blue-print plant. Today the blueprint is the expression of the finished work of the drafting-room and they are being used in an ever-increasing volume, especially by the Army and Navy Departments.

The photograph shows in operation a new blue-printing equipment, which is really three machines in one—printing, washing and drying by one continuous operation. No valuable space is taken up by open wash trays and there are no wet floors and no lines of dripping prints. The equipment occupies only 5' x 6'5' feet of floor space, and is clean and noiseless.

There is only one operator required. He stands in front of the printing machine, which places the tracings on the sensitized paper as it is passing thru the machine. Together the tracings and paper are carried up past a tank of powerful arc lamps, the tracings being returned automatically to the tray in front of the operator, while the exposed paper is carried back, passing first thru a bath of clear water, then thru a bath consisting of a weak solution of bichromat of potash or bichromat of soda, and lastly thru another clear-water wash, after which it passes up over the dryer and down into the rolling-up device at the back of the machine, where the finished prints are automatically wound up into a loose roll, perfectly free from wrinkles or distortions and ready for use. The entire process is accomplished without waste.

It is claimed that these machines have a capacity of five to six linear feet per minute, or 100 to 120 yards (the equivalent of 150, 24 x 36-inch prints) per hour, which has been proven to be as fast as an operator can properly handle the average run of tracings and keep the paper covered. At this speed the greatest economy is effected; no light or paper is wasted, and the prints are thoroly washed and evenly dried. By this method blue-prints of the finest quality are produced on either paper or cloth.

It may be stated that the electric dryer is provided with a series of switches so that the heat can be regulated in accordance with the speed at which the printer is being run.

The arc lamps are especially rich in the actinic or violet ray necessary for blue-printing. Each lamp is independently connected in at the bottom, and is controlled by a knife switch mounted in a metal box of approved design, which is located at the left-hand end of the machine. It is only necessary to burn a sufficient number of lamps to cover the width of the paper being printed. Thus again no electricity is wasted. There is a fan for circulating the air mounted on the left-hand end of the printer, and obviates all danger of breakage of the contact glass.
TREATING OLD MASTERS WITH X-RAY.

Interesting experiments have been conducted at Munich and Vienna in the examination of old portraits with Roentgen rays. One of the curators of the art museum used the X-rays on an old Madonna portrait and discovered evidence of a later overpainting. In Vienna, Prof. Max Dvorak applied the same test to a picture of the Mantegna School, which had been badly disfigured by later attempts at reconstruction. The X-ray photograph disclosed perfectly the original contour of the painting.

ELECTRIC ESCALATOR HANDLES RAILWAY STATION TRAFFIC.

Every railway terminal where the tracks are either elevated or depressed, or where passengers must be moved from level to level, will find the electric escalator or moving stairway of service.

The watchful and progressive railroad companies have spared no expense to make travel pleasant and comfortable, and now many of them are improving their terminal service by installing these escalators. The photo shows one of these interesting installations in the Pennsylvania Railroad Terminal in New York City.

During the morning hours the service is taxed practically to its capacity, about 11,000 people per hour. That the escalator is popular with the traveling public has been proved many times. Ninety-eight per cent of the people using this exit, travel on the escalator. The old-time stairway adjoining has been practically abandoned. No one will say his strength or waste his energy in climbing stairs when he can ride, and many people will walk considerable distances to ride one or two stories on an escalator.

The continuous stairway belt is driven by electric motors. They are so designed that the passengers' clothes cannot be caught and furthermore, the upper or lower floor levels the peculiar shape of the step elements causes the feet to be pushed off on the floor without danger of catching.

TREATING ROENTGEN RAY ILLS WITH RADIUM.

The Journal of the American Medical Association publishes a paper by Dr. Robert Abbe on "Roentgen Ray Epithelioma, curable by Radium, as Apparent Paradox," which was read at the last session of the association in San Francisco in May. The surgeon after citing cases wherein were effected cures ofRoentgen ray injuries, so common among those who work with the X-rays, says:

"I may say that no cases have presented themselves to me of chronic dermal Roentgen ray disease in the early stages of thick patches, cracked, ulcerated and painful, or of the epithelial growths of basal cell type on the back of the left hand of those who have in past years used that hand to test the tubes which have not yielded to radium therapy."

Dr. Abbe presented to a gathering of roentgenologists of the British Medical Association meeting two years ago the possibility of curing the disease in its early stage by radium, and most of the physicians present were skeptical but he met one from Australia who had found in his own experience that the application of radium had kept his hands well. Dr. Abbe said that no efficient action of radium is beneficial in the advanced stage of epitheliomas, so far as he can yet see, but in the early stage of the disease, he said, the cure may be assured.

He treated his first case in 1903. The patient developed typical epithelioma on the back of the left hand, and one application of radium cured it. There has been no recurrence after twelve years. Ten cases of physicians whose hands, disfigured by the Roentgen ray, were treated by him and all, he said, have shown the happy result of radium treatment.

"It seems almost a paradox of radiology," Dr. Abbe said, "that the accepted use of a large dose of radium from a Roentgen ray tube will cause a diseased condition of the skin which a similar radiation from a tube of radium will cure. This becomes intelligible when we know that the output of the Roentgen ray tube is almost wholly composed of hard, penetrating, irritating gamma rays." This is indeed good news.

ELECTRICAL EXPERIMENTER

In England the air warning signals are now supplemented by electric signs which flash out the unwelcome news as soon as

| London and All the Larger English Cities Are Now Supplied With Electric "Air Raid" Warning Signs. As Soon As a "Boche" Aerial Attack Is Imminent the Signs Flash "Take Cover"—When the Raid is Over They Show "All Clear." Electric Bells and Sirens Give the Audible Signal. |

| RADIUM IN GOLF BALLS. |

The use of radium in golf balls is explained in the following manner. It is not the radium itself, but the residue after the radium is extracted.

There is about 10 cents worth in the ball that is on the market now, which seems to be about the right proportion.

Uranium, which is the ore that radium is extracted from, is not expensive, but when it requires so many different processes to get the tiniest bit of the pure article, the cost amounts to a fabulous sum.

It is the heat in the radioactivity that warms the rubber and keeps the ball alive. Warm rubber will respond to the driver much quicker than if it were cold. Ouimet has used these balls with great success.
SINCE the introduction of the lightning rod over one hundred years ago by Benjamin Franklin, its adoption as a means of protection against destructive atmospheric discharges such as lightning bolts, has been practically universal. In a recent discussion on the subject of lightning protection, Dr. Nikola Tesla of New York, brings out many interesting facts not generally known concerning the real efficacy of the ordinary lightning rod as installed on houses, barns and public buildings all over the world.

Says, Dr. Tesla, "The efficacy of the ordinary lightning rod is to a certain degree unquestionably established thru statistical records, but there is generally prevalent, nevertheless, a singular theoretical fallacy as to its operation, and its construction is radically defective in one feature, namely its typical pointed terminal." In his new form of lightning protecting rod and ter-

more, inducing in the earth an equivalent area which a number of lightning rods could not neutralize in many years. Particularly to instance conditions that may have to be met, reference is made to an actual case in 1903 where it is probable that upon one occasion approximately 12,000 strokes occurred within two hours, all within a radius of less than 31 miles from the place of observation.

But also the pointed lightning rod is quite ineffective in the one respect noted, for the attraction effect, attracting lightning to a high degree—firstly, because of its improbable shape and secondly, because it ionizes and renders conductive the surrounding air. This has been unquestionably established in long continued tests with the Tesla wire-less transmitter above-mentioned, the inventor claims, and in this feature lies the recent disfavoring of the Franklin type of protector.

In Figs. A and B, different forms of such low density terminals and the arrangement of the same are illustrated. In Fig. A, there is a cast or spun metal shell of ellipsoidal outline, having on its under side a sleeve with a bushing of porcelain or other insulating material, adapted to be slipt tightly on a metal rod, which may be an ordinary lightning conductor. Fig. B shows another form of terminal made up of rounded or flat metal bars radiating from a central hub, which is supported directly on a metal rod and in electrical contact with the same. The specific object of this type is to reduce the wind resistance, but it is essential that the bars have a minimum area to insulate to least density, and also that they are close enough to make the aggregate capacity nearly equal to that of a continuous shell of the same dimensions. The general view of the building shows a cupola-shaped and earthed metal dome carried by a chimney, serving in this way the twofold practical purpose of hood and protector.

From the foregoing it will be clear that in all cases the new Tesla terminal prevents leakage of electricity and attendant ionization of the air. It is also independent of whether it is insulated or not. Should it be struck the current will pass readily to the ground either directly or, as in Fig. A, thru a small air-gap between. But such an arrangement is rendered extremely improbable owing to the fact that there are everywhere points and projections on which the terrestrial charge attains a high density and where the air is ionized. Thus the action of the improved protector is equivalent to a repellant force. This being so, it is not necessary to support it at a great height, but the ground connection should be made with the usual care and the conductor leading to it must be of as small a self-induction and resistance as practicable. Tesla has taken out a patent on this new lightning protector.

ELECTRIC VEHICLES IN NORWAY.

Electric vehicles are now receiving considerable attention and encouragement in Norway for every form of mechanical propulsion. Heretofore gasoline cars have been practically the only machines in use in the country. For the last year or two, however, electric cars have been received, and as there are but few electric cars in Norway, automobiles have practically disappeared.
Are Aeroplane Parachutes Practical?

By W. Edouard Haussler

The writer, who has been following aviation for the past few years, and who has had experience in actual flying, having owned an aeroplane, became interested in an editorial debate on the subject of “Aeroplane Parachutes” appearing in the New York Times, wherein Mr. Adrian Van Muffling, by profession a Chief Aero Engine Instructor at a New York Aeroplane School, gives utterance to such speeches as: “If an aeroplane comes down ‘out of control’ it is the duty as well as the natural tendency of the pilot to ‘stick it out’ and to do his utmost to regain equilibrium. If he happens to be high enough the chances are in favor of his doing so before connection with the ground is made. By the time he realizes that it is too late for him to right his machine before crashing it will be too late for the parachute to open, provided he could possibly manage to jump clear of it space.”

Wherein he shows that his estimation of the value of an aviator, the cost of whose training aggregates some $10,000, is less than the value of the machine in which he is flying and further that if the machine comes down out of control it is the duty of the pilot to come down with it, and calmly “stick it out.”

Were I to be granted the opportunity of seeing Mr. Muffling in a flying machine that was equipped with a “parachute,” despite his weak reasons why this is impossible, I am most positive that he would use the parachute in the case of an accident and would not adhere to the duty of “sticking it out.” The balance of his text explains in a large volume of words the idea that it is impossible to get out of the pilot’s seat and fall clear of the dropping plane, by the use of a parachute.

The diagram shown in the semi-circular illustration below will give the reader a clear idea of the various positions in which the machine may fall while out of control, and that in these positions the parachute will operate with sufficient certainty that a great percentage of the fatalities up to date could have been prevented.

It may also be of interest to make reference here to a parachute being used successfully in Rheims on October 10, 1913, by a young French aviator, Louis Renaul Piercer. He was the designer of the parachute device shown in our illustration and he attached his invention to a Nieuport monoplane. On the day that he made his test flight, he sat in the observer’s seat and had the parachute strapped to his shoulder belt. Another aviator piloted the machine. The weather was squally and he was warned not to make the trip; he, however, started, heedless of the admonition and when about 2,000 feet in the air and making a turn, a sudden gust of wind struck his right plane and crumpled it. His life was saved by his parachute device, while the pilot “stuck it out” and was killed!

Piercez was killed in 1914 in an automobile accident, and his device has not been explored any further, except by the Huns. The action of the device is simple and easy to understand. The lever marked A, is pulled when it is desired to release the parachute which is placed on the upper side of the fuselage.

The puling of the lever causes air curtain C, to slide down or up, according to the position of the machine. It is spring loaded and is forced down with a snap. The forward or downward motion of the plane causes a rush of air which fills the parachute and lifts the pilot free of the machine; the machine dropping from under him. It therefore becomes apparent that he has not so difficult a task to become free from the machine as Mr. Muffling would have it. The Times editors, who are very keen on correcting letters from the readers that may in any way be misunderstood, make comment on Mr. Muffling’s letter, under the heading of “His answer hardly convincing” — wherein one of the paragraphs is directly to the point and fully coincides with the writer’s ideas on the subject. This editorial paragraph in part read: — “that if this device were always at the aviator’s command some of the fatalities that now occur could be prevented, or that to have the lives of even a few of these enormously valuable men would be worth while. Still less did the expert’s argument meet the fact that, according to a report of trustworthy origin, a German aviator was seen, this week, to extricate himself and a parachute from an airplane that was falling in flames.” And that an aviator “is not a man who can be replaced by the first man on whom the Government is willing to make another like expenditure. He is literally a rare bird and to lose him unnecessarily is worse than unwise.” Therefore one may readily see that even the daily press is not falling in line and “gobbling up” mere mention of a certain thing being impossible, and letting it go at that. We are now living in an era where impossible and can not should be stricken from our vocabulary. This is the age of wonders and when an idea does not work against the principles of Nature, it is possible. At least let us try it out thoroly.
Popular Astronomy

THE PLANET MARS—FOURTH PAPER

By ISABEL M. LEWIS
Of the U. S. Naval Observatory

As a result the distance of Mars from the earth at opposition, when it is best seen, varies from thirty-five million miles for a near or favorable opposition to sixty-one million miles for a distant or unfavorable opposition, depending upon the position of Mars in its orbit at the time of the opposition. Of course the apparent diameter of the planet’s disk and its brilliancy are considerably less when opposition occurs near the aphelion point in its orbit than when it occurs near the perihelion point. The relative brightness of the planet in the two positions are in the ratio of one to four. Favorable oppositions of the planet occur every fifteen or seventeen years and at such times the unusual brilliancy of the planet makes it a most striking object in the heavens, the rival of Jupiter in splendor. Furthermore, Mars is always easily distinguished from all the other planets by its deep red tint.

The year of the Martians, granted there are such, is 687 days, or 1 year 10% months in length, but the time that elapses between successive oppositions of Mars with the earth is greater, due to motion of the earth in the interval. It is equal to 780 days or a little more than two years. Since all observations of the planet, which can only be made satisfactorily near the time of opposition, are obtained in alternate years for several months preceding and following the date of opposition.

The equator of Mars is inclined nearly twenty-four degrees to the plane of its orbit, which is about half a degree more than the inclination of the earth’s equator to its orbit. As a result Mars has a year very similar to our own, a little more pronounced, since the inclination is greater, and nearly twice as long since the Martian year is nearly equal to two of our years.

Observations of surface markings on Mars have been recorded for more than two hundred and fifty years, the earliest observations being those of Hooke and Cassini in 1666. One result of these long continued observations has been a very accurate determination of the length of the Martian day, or the period of its rotation on its axis, which is given as 24h 37m 22.6s. This value is in error less than two hundredths of a second and shows to what a high degree of accuracy it is possible to determine certain astronomical results.

Mars, then, closely resembles the earth in the length of its day and night.

The mean annual temperature of the earth is 60° Fahrenheit. If it were situated at the distance of Mars from the sun it would receive per unit area only 43% of the light and heat that it now receives and it can be shown that its temperature would be 39° below zero on the Fahrenheit scale. If, then, the atmosphere of Mars were similar in composition and density to our own and if the nature of surfaces of the two planets were the same, two very doubtful assumptions, the temperature of Mars would approximate —35° F. There are reasons for assuming that this estimate of the average yearly Martian temperature is much too low. Prof. W. H. Pickering, one of the leading observers of the planet Mars at the present time, advances evidence to show that the mean daily temperature at the Martian equator throughout the year cannot be far from the freezing point and that tropical fogs are to be expected at any Martian season and, in fact, have been observed during the opposition just past in the Martian morning.

Even the early observers of Mars with the aid of telescopes far inferior to the best instruments of today were able to mark prominent markings of the planet’s surface.

Two Views of the Planet Mars, Photographed With the Mount Wilson 60-Inch Reflector. The Large View is a Photo Taken on October 4th, While the Small Photograph Was Taken on November 3rd. At the Time the First Picture Was Taken Mars Was Near Opposition and Consequently Showed Up Much Larger Than When the Second Picture Was Taken As By That Time Mars Had Receded Quite a Good Deal and Therefore Appears Smaller.
Two Different Views of the Planet Mars. As Mars is Turning On Its Axis Once in Every Twenty-four Hours the Same as the Earth, We Are Able to See the Entire Surface of the Martian Globe During That Time. The Views Shown Here Are Taken Six Hours Apart From Each Other. Photographs Were Made During the Opposition of 1911 When Mars Was Some 47 Million Miles Distant From the Earth. In 1924 the Two Planets Will Be About 36 Million Miles Apart, the Smallest Distance Ever Reached Being 35 Million Miles. Photos Show the Top South—the Bottom North, as in the Telescope All Objects Are Turned Upside Down. The Southern Cap Is Not in Evidence, It Having Already Melted At the Beginning of the Martian Summer. The Melted Water Has Been Conducted Equatorward By the Canals. The Light Areas Are Supposed to Be Deserts. Nearly All Canals Are Perfectly Straight, the Ones Near the Edges of the Photograph Appearing Curved Only Because We Are Looking on a Globe and Not on a Plane Surface. Photo Courtesy of the Late Prof. Percival Lowell, Flagstaff Observatory, Flagstaff, Ariz.

the white polar caps and their seasonal changes, the reddish or orange-colored tracts that cover five-sevenths of the planet's surface and which they spoke of as "deserts," and the greenish or greenish-grey regions which they incorrectly named "maria," considering them to be seas or lakes.

In the year 1877 occurred one of the favorable oppositions of Mars and this date was epoch making in the study of the planet for it marked both the discovery of the two tiny moons of Mars, Deimos and Phobos, by Prof. Asaph Hall, with the 26-inch equatorial, which had just been installed at the U. S. Naval Observatory and the discovery of the far-famed "canals" by the Italian astronomer Schiaparelli at Milan. This keen-eyed observer of Mars noted at the extremely favorable oppositions of 1877 and 1879 a number of fine, narrow, dark lines crossing the orange-colored regions in all directions and usually connecting the maria or dark regions. Schiaparelli gave these markings the name of "canali," meaning "channels," which has been translated, rather unfortunately, into "canals." Whatever the nature of these peculiar surface markings they bear no resemblance to terrestrial canals. The more conspicuous of these markings average from one thousand to two thousand miles in length and from one hundred to two hundred miles in width. Schiaparelli's discovery of the canals was confirmed by a number of observers, including Perrotin and Thollon at Nice, the late Prof. Lowell, who observed the planet continually under excellent atmospheric conditions at Flagstaff, Arizona, from 1894 to the date of his death in 1916, and Prof. W. H. Pickering of the Harvard College Observatory, who started observations of the planet in 1880 and is now observing it at Jamaica under atmospheric conditions as fine as are to be found at the Lowell Observatory at Flagstaff. Prof. Lowell's observations of Mars are being continued at this observatory under the able directorship of Dr. V. M. Slipher, who was Prof. Lowell's assistant for many years. There are, however, many skillful observers who have been unable to see the canals, tho they have been added by the largest reflectors and refractors in the country. Such observers include Barnard, with the 40-inch Yerkes refractor; Hale, with the 60-inch Mt. Wilson reflector, and Prof. W. W. Campbell and other observers at the Lick Observatory. All these observers see a great variety of other surface markings, however. The canals of Mars are as much the subject of discussion and controversy to-day as they were twenty-five years ago and the reality of the canal system is still denied by certain astronomers.

The discovery, made by Lowell and a number of other observers, that the canals traversed the maria or seas as well as the desert tracts and also the variety of shade and detail visible in these dark green or greenish-grey regions, led to the gradual abandonment of the early belief that they were bodies of water. They are now believed to be marshy tracts of vegetation that are watered by the melting of the polar caps during the spring and summer seasons. A dark blue line is always observable on the border of the melting polar cap and since this dark line is not to be seen except when the polar cap is decreasing in size, or melting, it seems to prove conclusively that the Martian polar cap is similar to the terrestrial polar cap and consists of snow and ice. Moreover, the melting of the cap is attended by a decided darkening of the canal system and the greenish regions due, one would naturally assume, to the quickening of vegetation with the advent of spring.

The theory held by the late Prof. Lowell, that the canals are strips of vegetation bordering water-ways or irrigation ditches, built by intelligent beings to conserve the water supply of the planet, which is believed (Continued on page 428)

Nine Different Telescopic Views of the Planet Mars Taken With the Yerkes 40-Inch Refracting Telescope at Short Intervals. A Slight Shift of the Martian Configuration Will be Noted Due to the Rotation of Mars on Its Axis. The Brilliant White Spot at the Top is the South Polar Snow-Cap and It is Summer in the Southern Hemisphere of Mars.
The Gyro-Electric Destroyer

ALTHO the Electrical Experimenter has only been out for the past ten days, as we go to press with this article, and tho the September issue of this magazine is not as yet in the hands of most of the readers, I feel rather encouraged at the result of my last month's article. In that issue, as will be remembered, I took the advice of several readers who suggested that I build a model of the Gyro-Electric destroyer, the latter to be turned over to our Government. The funds were to be supplied by "Experimenter" readers.

The magazine was hardly out in New York before many people whom I had never seen before began pouring into my office with their dollar bills and signed blanks. All were enthusiastic and earnest about the idea, all glad to be permitted to "do their bit" and to "wipe the Hun artillery from the face of the map," as one elderly gentleman put it when shaking hands with me and wishing luck to the enterprise. Then remittances began to pour in, in amounts from $10.00 down ward, and while the amounts so far received are relatively small, due to the fact that the magazine at this time of writing is hardly in the hands of 5% of our readers, all signs point to the actual building of the Gyro-Electric Destroyer.

In the November issue will be printed the first list of readers who subscribed to the funds, as well as the total amount collected up to that date. All amounts received up to September 23rd (the closing date for the November issue) will be found in the next issue.

This month I will content myself to print a few extracts from the letters of enthusiastic contributors to the Gyro-Electric Destroyer Fund. Here they are:

EVERY LITTLE HELPS.
"...I am a regular E. E. reader and have watched the development of the idea from the start. I also have faith in it and therefore my support, although it may be small, will help if all of the readers are as faithful and patriotic. Wishing you success in the matter, I remain yours truly,

The Gyro-Electric Destroyer, a 45-Foot Monster, Built of Steel and Running at High Speed, Due to its Large Circumference, Easily Rides Over Shell Holes and Trenches and Other Formidable Obstacles. Its Use Is Mainly to Harass and Pout Out of Action Enemy Artillery by Either Grinding it Into the Ground or Otherwise Bomb the Artilleries With Their Guns Out of Their Positions. Experimenter Readers Are Going to Build a Model of This Machine to Be Turned Over to "Uncle Sam." The Above Illustration Shows the Front Cover Illustration of the Largest French Scientific Monthly Featuring This American Destroyer.

THINGS I NEED IN MY LAB: But if you need another dollar let me know so I can help wipe the Hun out of the world. I have faith in the Gyro-E.-D."
T. D. Cooper, Winterville, N. C.

WE TOO HOPE!
"Hope all the other 'Bugs' do the same."
Theodore Collins, Kewaunee, Ind.

I HAVE FAITH.
"I have read 'Modern Electronics' and the Electrical Experimenter ever since they first started. I have faith in your Gyro-Electric Destroyer. Go to it and if more money I needed I can help a little at least." Yours for success,
F. A. Barber, Manager of Service Department, Boxwood, De Fennes & Fellon, Master Cinematographers, Wilkesbarre, Pa.

ASTOUNDINGLY INTERESTING.
"...In my estimation it is an 'astoundingly excellent' idea. I would like to wish the best wishes for its early completion."
Yours,
Walter E. Hoagland, c/o M. L. W. P., Co., Maya Landing, N. J.

GOOD LUCK—AND A P.S.
"Good luck to the current and to the Gyro-Electric Destroyer, and to you and to your organization. P. S. I may come across with another dollar for the 'G. E. D.' in a few days."
A. L. Terry, 1422 Hurt Bldg., Atlanta, Ga.

"IT IS MY DUTY."
"I am not sending you this dollar because I want my name published in your magazine, but because I want to do something for you because it is my duty as an American citizen under the protection of the Stars and Stripes. Thanking the originator of the idea and yourself I remain yours,
"Jeremiah L. Westheimer, 3707 Washington Ave., Avondale, Cincinnati, Ohio.

As a sign of the times, and merely to show what others think of the Gyro-Electric Destroyer, we reprint herewith the cover illustration of the famous French monthly Science et la Vie (Science and Life).

Science et la Vie is the greatest and most widely read French popular scientific magazine. It is a really great publication, the current issue of course is a matter of number, numbering 192 pages. They choose for their cover illustration, which is printed in four colors, the Gyro-Electric Destroyer (Cont. on page 389)
Autumnal Uses of the Electric Fan

By Grace T. Hadley

HERE are the latest directions for drying fruits and vegetables before an electric fan:

All the vegetables must be thoroughly washed and dried and in the case of root vegetables pared thinly, then sliced as thin as possible and placed on cheese cloth over racks. Then start the fan. Have it at an angle of about 30 degrees so there may be a slightly upward current of air thru the racks.

Vegetables such as turnips, carrots, etc., if allowed to stand for about ten minutes (after slicing) in a 4 per cent. water solution (1 teaspoonful salt in 1 qt. water) will not discolor in the drying process.

Corn should be put into boiling water for—from five to ten minutes to set the milk before the cutting from the cob; then spread the cut corn upon the cheesecloth.

Green vegetables such as string beans and wax beans should be blanched in hot water, for from five to ten minutes before drying.

Fruits such as berries are merely thoroly washed then placed on racks to dry. These will take a little longer to dry because of the somewhat higher water content. Berries are dried enough if they do not stain the fingers when pressed.

Other fruits and vegetables should have a pliable, leathery appearance when dry and should not be dried so long that they become brittle.

It is best not to pack and seal the dried products for several days, but keep them in open trays or pans covered with a clean cloth. If the products appear to be too moist they should be returned to the drying racks for a short time. Ability to judge accurately as to when fruit has reached the proper condition for removal from the drier can be gained only by experience. It should be so dry that it is impossible to press water out of the freshly cut ends of the pieces, yet not so dry that it will snap or crackle.

Two other practical uses for the electric fan in hot weather are illustrated herewith—the first, that of drying dishes by blowing a breeze over them and the second, cooling electric lamps for the city which were formerly imported chiefly from the General Electric Company in America. The fact is pointed out in the report of the Japanese consul-general at that point.

Splicing links and a unit made of a non-conducting material have been invented for insertion in electric light chains to assure that they are insulated.

AN ELECTRIFIED CAT.

A cat has been in the habit of sleeping on a rubber mat under a dynamo in Cleveland's power house, runs the yarn in a Cleveland paper. Somebody removed the mat and the cat slept on an iron plate. It didn't seem to hurt the cat, but her fur became so charged with electricity that ever since it has stood stiff on end like bristles of a hairbrush.

(Perhaps the cat's hair was scared stiff! Ed.)

The chief inventions used in the present war as distinguished from the Napoleonic wars are: Steamship, submarine, aircraft, high-power guns, smokeless powder, breech- loading guns, rapid-fire gun, revolver, automatic pistol, telephone, wireless telegraphy, automobile, poisonous gas. Yes, and German "Peace-Offensives!"

AIR MAIL PILOTS GO THRU THUNDER STORMS.

The air mail pilot is solving the problem of flying in all sorts of weather. Prior to the establishment of the Air Mail Service it was regarded as impracticable to make flights with airplanes during severe storms.

The practise of this daily service has shown that the mail can be carried thru the air in the teeth of a storm. On three or four occasions the air mail pilots have encountered severe thunder and lightning, wind, hail, and rain without being apt when in flight. No flight attempted in a storm has yet failed.

Recently Lieut. Stephen Bonsal from Philadelphia to Washington ran into a violent thunderstorm at Laurel, Md., at an altitude of 5,000 feet and proceeded on his way to the landing field in Washington without interruption. It was impossible to distinguish any landmarks in such torrents of rain. When he descended to a lower altitude for observation he was near the wireless towers at Radio, Va. To observers he appeared to drop out of the clouds from nowhere at an angle of 45° to a height of about 300 feet when he leveled the plane and made a perfect landing at Potomac Park in the midst of a torrent of rain. The plane arrived on schedule time, not being delayed by the storm. The propeller was slightly damaged by the pelting rain.

Lieut. Bonsal was not assisted by radio guide but depended entirely up on his compass and his judgment from familiarity with the route.
CURRENT ELECTRICITY (concluded)

EXPERIMENT 93

Insert a piece of soft iron in the helix shown in Lesson 15, and allow the current to pass thru the helix. On testing the strength of the poles now (by bringing the helix near a compass or by picking up iron filings) we find a great increase in the magnetism. The iron core which was inserted has been magnetized by induction just as if it had been placed in the field of a permanent magnet; and now we have added to the magnetism of the helix the magnetism of the core, which accounts for the increase in strength. A helix with a core is called an electro-magnet, the commercial form being usually in horse-shoe form (see figure 84-A) in order to double the strength of the magnet. Figure 84-B shows the arrangement of the lines of force thru an electro-magnet m, and its armature a (piece of soft iron) which cuts off the force passing thru the magnet. The strength of an electro-magnet depends upon the ampere-turns (product of the amperes or amount of current, times the number of turns of wire in the helix). The importance of the electro-magnet in modern electricity cannot be over-estimated. One has but to recall its use in the bell, current measuring instruments, motor, dynamo, telephone, telegraph, induction coil, and an indefinite number of devices.

EXPERIMENT 94—The electric bell illustrates the use of the electro-magnet to produce an intermittent action. The construction is simple (see figure 85); c and f are binding posts, d a screw with platinum point, e a flat piece of spring steel, fastened to binding post g, and to a hammer consisting of hairpin with ball-bearing soldered to the end, i is gong, and k an electro-magnet consisting of two spools wound with magnet wire, two screws for cores and iron nail connecting the cores.

On closing the switch b (equivalent to pushing the button) current flows from battery to binding post f, from f thru connecting wire to the magnet, from the magnet to the binding post g, from g thru the spring steel to screw d and thence out thru binding post c. The passing of the current causes k to become magnetized, and k draws the spring steel toward it, thereby breaking the contact at the screw d. This causes the current to suddenly stop, and its effect is to magnetize the spring of the steel causes it to snap back to the screw which closes the circuit again; the current then flows thru the magnet once more. These operations are repeated over and over again as long as switch b remains closed. Hence the hammer is alternately drawn to and pulled away from the gong, and the bell “rings.”

EXPERIMENT 95—Cut in half a lead pencil having a large size lead. Shave off the wood from the lead; connect the leads thru a battery of about thirty volts, and separate the leads about an eighth of an inch. An arc will be formed similar to that of the commercial arc lamp, but of course not as bright. After a few minutes cut off the current and examine the leads. One will be found to be concave and the other convex. The concave is the positive and the convex the negative. (The polarity can be determined as suggested in Lesson 15.) This is just as you might have expected; for the current is going from + to — has carried some of the carbon with it and deposited it on the other electrode. Try bringing the leads as close together as possible without their touching. No arc will be formed unless the leads are first touched together. If the leads are not touched together the resistance of the air prevents electricity of such low voltage from passing thru the gap however small it may be. But when the leads are first touched together and then drawn apart (the heat of the current while the leads are in contact vaporizes the leads and fills the gap with carbon particles which offer but slight resistance to the passage of the current); the current now passes thru the gap and the hot particles glow. Using regular commercial carbons and the proper voltage (50 volts) an arc of great brilliancy is obtained. In the more up to date forms the carbons are impregnated with lime, magnesia, silica, or other minerals which give off a very brilliant light when heated to incandescence.

Figure 86-A, shows a three wire "hook-up" for controlling current from two different points. This hook-up is extensively used where it is desired to control a source of electric power. (See figure 86-B) cd are single double throw switches (or the two button type). The middle wire is used as the neutral, and connections are made to the outside wires. If b and d are closed, the circuit is closed and current passes thru the lamp L. If person at the left wishes to extinguish the light he opens b and closes a—b and c now both being open, the circuit is open. The person at the right can open or close the circuit by similarly manipulating the switch d. (The reader should try all possible combinations of the switches ab and cd and trace out the various paths of the current.)

EXPERIMENT 96—No doubt Oersted’s discovery of the magnetic effect accompanying an electric current thru a conductor led to Sturgeon’s discovery of the electro-magnet in 1825, six years later. Sturgeon’s discovery in turn attracted the attention of physicists the world over, to the production of an electric current by means of a magnet (the electro-magnet being so much more powerful than the ordinary magnet). The year 1831 marked the beginning of modern electricity when Joseph Henry in America and Michael Faraday in Great Britain discovered independently and simultaneously the dynamo principle. Now electricity on a commercial scale for the production of light heat and power was possible. The principle is simple and can be easily understood without recourse to the intricacies of the modern dynamo.

Wind a coil of about 500 turns of number 22 copper wire, with a diameter of about two inches. Connect this coil with a galvanometer or other current detecting device. A simple galvanometer can be made by suspending a coil of about 200 turns of number 30 copper wire between the poles of a strong electromagnet (see figure 86-B). Thrust the coil c down over the S-pole of the magnet. The deflection of the needle P of the galvanometer will indicate that a current is passing thru the coil. If, how-
New Developments in Telephotography

By LeROY J. LEISHMAN.

A cathode ray may be diverted from its path by a magnet, and the same thing is true of many other rays. Quite a variety of optical effects may be produced in a magnetic field, many of which lend themselves to the uses of telephotography because the effect of gravity and friction is not felt, and the inertia is nil, compared with mechanical ways of receiving. In a rough manner, these rays may be used by causing them ordinarily to pass over an electromagnet thru the aperture of the dark box; they work as fast as the lag in several hundred miles of wire will permit them.

Without synchronism, telephotography would be impossible. In my previous article, I explained a manually controlled synchronizer, and made reference to an automatic system. In connection with this machine, I have arranged automatic starting and stopping features.

When the machines are not in operation, the starting relay on the receiver is connected direct to the binding posts, to which

This Diagram Shows the Electrical Connections and Arrangement of the Various Apparatus in Mr. Leishman's Newest Telephotographic Instrument, Intended for Transmitting Pictures Over Telephone or Telegraph Wires. Among Other Interesting Departures the Inventor Makes Use of a Novel Polarized Light Ray, Which Is Deflected by an Electromagnet.

---

are attached the wires from the sending machines. The arm of this relay is held by gravity against a contact to effect this connection. The arm is then inclined about 15 degrees from the perpendicular. When the sending machine starts, the first impulse causes this relay to pull its arm against a different contact, against which it is held by gravity, as the position is 15 degrees the other side of the perpendicular. This breaks the relay connection and starts the motor which operates the machine.

An important part of the synchronizer is

Original "Valves" Used by Dr. J.A. Fleming

Professor J. A. Fleming in 1904 was the first to apply the phenomena of thermionics to the rectification of alternating electric currents, whether of high or low frequency.* The device which he made to effect this may take one of several forms, some of the original ones of which are shown in the photograph herewith. It consists of an ordinary carbon filament incandescent lamp provided with a separate insulated electrode, in the shape of a flat or cylindrical metal plate, or another carbon filament, sealed into the bulb. When the carbon filament is rendered incandescent by a source of electric current it will be found that a single cell will pass a current thru the vacuous space between the insulated electrode and the hot filament provided that the negative pole of the cell is connected to the negative side of the filament. If the connections of the cell are reversed, practically no current passes, the small amount of current obtained being due to positive ions formed from the residual gas in the bulb. This is what we should expect from the fact that the hot filament is emitting negatively charged particles, and in order to draw these across the gas space to the cold electrode the latter must be raised to a positive potential with respect to some portion of the incandescent filament.

The space between the cold and hot electrodes, therefore, possesses unilateral conductivity, and the arrangement acts as an "electrical valve", passing electric currents in one direction but not in the opposite direction. Fleming next found that this device could be used, on this principle, to convert either audio or radio frequency electric oscillations into unidirectional currents, which may then be detected by means of an ordinary galvanometer.

Fleming found later that greatly improved results were obtained when the valve was constructed with a tungsten filament and an insulated copper cylinder surrounding it. This is due to the fact that the tungsten can be raised to a much higher temperature than carbon without volatilisation and gives a much greater electronic emission, and this type of thermionic valve is almost universally constructed at the present time with either a tantalum or tungsten filament.

The next step in the evolution of the thermionic valve was made by Dr. Lee de Forest and consisted in the introduction of a third electrode into the evacuated bulb. Lee de Forest had been working on the simple rectifying valve containing a metal or carbon filament and one insulated electrode (already described) at practically the same time as Fleming, and his results were first described in a paper before the American Institute of Electrical Engineers in October, 1906. Considerable controversy has since then ensued as to the relative priority of the inventions of the Fleming valve and the "Audion", the name assigned to the valve by de Forest; but this has now been settled in favor of Fleming for the original valve, Lee de Forest having the credit of introducing another insulated electrode into the bulb, thereby transforming it from a rectifying valve into a kind of gas relay, having an amplifying effect on the received oscillations.—Photo courtesy Wireless World.

AN UNUSUAL TYPE OF ELECTRON RELAY.

The hot filament rectifier or electron relay illustrated herewith is of rather unusual type, being encased in a perforated aluminum jacket, made from an individual egg boiler.

The advantage of the construction shown lies for the most part in the decrease of filament current required, due to the heat being retained by the metal covering.

Three connections are made to the inside of the bulb and the fourth to the outside shell.—R. U. Clark, 3rd.

*See British Patent 24,850—1904.
THE type of radio frequency Hot-Wire Meter shown in Fig. 1 is of extremely low resistance and is designed to operate at a low temperature, thereby allowing a heavy overload without burning out as well as keeping the case from heating up. This low resistance insures a minimum of losses in the circuit. It is made in two models, flush and full case type, measuring 3 inches in diameter. The meter is contained in a portable aluminum case suitable for laboratory uses. The expansion strip is of thin platinum and defies oxidation which gradually changes the readings of most instruments of this type. The steel shaft is supported by sapphire bearings and a zero adjusting button on the front of the instrument allows instant calibrating of the pointer. The range of the meter varies from 1/2 to 10 amperes. It is finished in satin black and all of the parts and movements are interchangeable.

The new radio frequency Decade Bridge (Fig. 2) is made up of resistances in suitable arrangement for bridge measurements adapted to the measuring of inductance, capacity and resistance at high frequencies, using a sine wave generator or oscillating vacuum tube, as well as to D.C. measurements. Its operation is identical to the Wheatstone bridge. In measuring capacity and inductance on this bridge, one arm of the bridge compensates for the resistance of the capacity or inductance under measurement as compared to that of the standard, thus giving an indication of the resistance as well as the capacity and inductance at the particular frequency employed. The bridge is mounted in a compact and convenient cabinet and arranged to eliminate losses at high frequencies. This bridge is accurate up to 1,500,000 cycles.

Fig. 3 illustrates the latest development in the form of a Vernier Condenser a Finely Graduated Capacity is Attainable. This Instrument Makes a Laboratory Condenser of Any Variable Capacity, Fig. 3.

With This "Vernier Condenser" Shunted Across Any Standard Variable Condenser a Finely Graduated Capacity is Attainable. This Instrument Makes a Laboratory Condenser of Any Variable Capacity. Fig. 3.

The Telephone Transformer (Fig. 4) is designed to give a large field of variable inductance values and that represents its advantage over the old type of open-core telephone induction coil or Audion transformer now in use. It is substantially constructed and will stand rough usage. The eight binding posts on the front hard rubber panel make it very simple to connect into a circuit for any desired inductance ratio very readily. Photos courtesy General Radio Co.

THE GYRO-ELECTRIC DESTROYER.

(Continued from page 384)

The Gyro-Electric Destroyer, presumably because the French scientific editors thought the machine feasible. The copy featuring the machine is the July 1918 issue and reached New York just as the September issue of the EXPERIMENTER had gone to press.

If the French scientists have faith in the Gyro-Electric Destroyer—and they surely ought to know—EXPERIMENTER readers should back up an America idea for all that it is worth. I firmly believe that the machine is thoroly practical and feasible. And I am just as certain that if we had twenty of these machines in France just now with which to grind the Hun artillery into the ground, or by blowing it to pieces, the war would be ended much sooner. Deprive the Huns of their guns, and we will have them back to the Rhine in no time. This is a machine war—let's have the best machine. In the meanwhile—if you share this view with me—you might sign the subscription blank.

H. Gernsback.

Using a modified wireless receiving instrument, a French scientist has been able to detect thunder storms more than 300 miles distant.

PIPING UNDER SAYVILLE WIRELESS.

A Mineola contractor in the use of his steam traction trench digger has just completed an extensive underground piping system at the Sayville Wireless Station, which adds to the efficiency of this huge wireless plant, now such an important factor with the United States Government.

U. S. SHIPS HEAR "HUN" RADIO TO U-BOATS.

Wireless operators on an American and other ships crossing the Atlantic at night frequently "pick up" orders being sent by the German Admiralty to submarines at sea. The messages are in code, of course, and the submarines never acknowledge receipt of the orders, because if they did some war-ship of the enemy might get a clue as to the location of one or more of the undersea boats.

These messages to the submarines are from Nauen, a small town near Spandau, where Germany has its great wireless station. Electrical waves produced there will reach some 6,000 miles.

Nine towers are in use, the highest being 850 feet. Last year Nauen sent to the outside world almost $2,500,000 for the German government.

Recent Design of Hot-Wire Ammeter. Calibrated for Radio Frequency Measurements. It Possesses an Extremely Low Resistance, a Much Desired Quality in All Such Instruments. Fig. 1.
The Revolving Mirror and Spark Discharges

By PROF. LINDLEY PYLE, Professor of Physics, Washington University

It is a matter of historic interest, especially to wireless enthusiasts, that an American physicist, Joseph Henry, first secured, in 1842, indirect experimental evidence of the oscillatory discharge of a Leyden jar; that Lord Kelvin, in 1855, made the mathematical prediction that the time elapsing during an oscillation is given by the now familiar equation, \( T = 2 \pi \sqrt{\frac{C}{L}} \); that Feddersen, in 1857, obtained direct experimental evidence of the oscillations by examining the spark in a rotating mirror; and that Hertz, in 1887, showed experimentally that there is an accompanying electromagnetic wave propagated outward into space, thereby explaining certain puzzling experiments performed by earlier experimenters, and inaugurating the marvelous development of wireless telegraphy.

The amateur electrical experimenter may easily repeat Feddersen's classic experiment and measure to his own intense satisfaction the number of to and fro surgings per second in the discharge of a condenser thru an inductance and low resistance. This number is, of course, the number of waves thrown off into space per second. Since in one second the wave motion travels out into space 186,000 miles, the wave length in miles is immediately found by dividing 186,000 by the rate per second at which the waves are produced.

Figure 1 shows the arrangement of the required apparatus. A small transformer, \( T \), is used to charge a capacity (condenser), \( C \), arranged so that discharges take place thru the inductance, \( L \), across the spark gap, \( g \). The spark gap device consists of two zinc rods thrust thru holes bored in the sides of a wooden box, the box completely enclosing the spark except on one side where a hole is cut (see dotted outline of box in Fig. 1). The box may be about six inches along its edges and the gap should be about one-eighth of an inch long. Light from the spark passes out thru the hole in the box, thence thru a lens, \( l \), to a piece of good plate-glass mirror, \( m \), from which it is reflected back thru the lens to a focus on a photographic plate at \( P \). The mirror is fastened upon the projecting shaft of a small high-speed motor in the manner indicated in Fig. 2. (In fact, there are two mirrors.) Referring to figure 2, \( w \) is a piece of wood bored to fit tightly upon the motor shaft; \( m \) and \( M \) are two pieces of good quality plate-glass mirror fastened securely to the wood by red sealing wax. The lens should be bought at an optician's shop. Ask for a spectacle lens of one diopter focal power, i.e., one whose focal length is one meter, or 39.4 inches. It should not cost more than fifty cents when bought with the unfinished edges. The lens should be held in a stationary support facing the spark gap at a distance therefrom of 39.4 inches, with the motor driven mirrors as close as possible behind the lens (see Fig. 1). The faces of the mirrors should be as large as the face of the lens.

With the spark discharge in action (switch \( K \) closed) and the motor at rest, one should then be able to obtain a bright and sharp image of the spark upon a piece of white paper held at point \( P \) at the side of, and close to, the spark-enclosing box. (It will be necessary to shift the position of the motor armature by hand until the beam of light reflected from a mirror falls in the right direction.) More the armature slowly by hand and a number of separate images of spark discharges appear upon the white paper. Each separate image corresponds to a separate crash of noise coming from the spark gap and corresponds to the discharge phenomenon following each charging of the capacitance \( C \). We now proceed to show that when the armature rotates at a high speed each of these separate patches of light will itself be found to be broken up into separate discharges, meaning that the discharging of the capacity \( C \) really consists of a to and fro surging of electricity across the spark gap—each to and fro surging corresponding to an electromagnetic wave "shaken off" into surrounding space. The appearance of the discharge is then reproduced in Fig. 3. It can be seen directly on the white paper screen when the motor is at high speed but it is better to register the effect upon a photographic plate.

DARKEN the room or work at night in an unlighted room. Place a fresh and extra-rapid photographic plate in the position \( P \), with the sensitive face pointed toward the lens. It is most convenient to put the plate into a regular plate holder, if one be available, and to draw the slide just previous to the exposure. Start the motor and when it has attained its highest speed close the switch in the primary circuit. Now watch the face of the exposed photographic plate to see when the light of the spark falls upon it,—for it is obvious that only when the spinning mirrors happen to be in a certain position will they throw the light to the plate. Several records may be obtained upon the same plate provided it be moved slowly sideways to avoid having a spark image fall upon the same part of the plate twice.

It is now plain that the box is placed around the spark gap so that there may be no fogging of the plate by stray light while exposure is being made. Shut off the spark and the motor, develop the plate, and, if careful, you will have succeeded in taking a picture like that illustrated in figure 3.

The photographic reproduced in figure 3 was obtained by using 6 one-gallon Leyden jars connected in parallel to give the capacity \( C \) and 8 turns of a helix of 12 inches diameter whose turns were one inch apart furnished the inductance \( L \). In this case the photo plate was 58.7 inches from the lens and the motor was revolving at the rate of 3,764 revolutions per minute, as measured by a speed counter. The speed at which the spot of light crossed the photo plate may be easily calculated if it be recalled that when a reflected beam of light comes from a revolving mirror the beam turns twice as fast as the mirror. (For example if a looking glass receiving a sunbeam is turned thru 45° the reflected beam is turned thru 90°.) In the present case the beam of light coming from the lens is turning at the rate of twice 3,764 revolutions per minute, or 125.5 revolutions per second. Hence that part of the beam at a distance of 58.7 inches from the lens has a speed of 2 x 3.1416 x 38.7 x 125.5 = inches per second, or 40,280 inches per second, or 3,857 feet per second.

In other words, the spot of light from the spark crosses the plate at a speed much greater than that of a rifle bullet. Furthermore careful measurements on the photographic showed that there were 483 complete and three surges in oscillographs recorded.

The author will be happy to supply copies of this photographic device and an instruction book for the cost of materials, which is about forty cents, and for the cost of workmanship, which is about twenty-five cents. The necessary apparatus may be purchased at the cost of fifty cents. The time of exposure is about a minute. The author will be pleased to answer any questions that may be sent to him regarding this photographic device.

223,500 oscillographs per second. The photographic reproductions took place before the energy of this particular discharge was dissipated, but meanwhile 20 wireless waves were thrown
The Einthoven Galvanometer

By SAMUEL D. COHEN

PART II.

The next important thing is the tele-
scopic apparatus, Figs. 13, 14. The frame
for this is shown in Fig. 18. It is
made of brass, and in this job it
will be necessary to use a lathe and
turn it down very accurately to the diame-
ters given. The lens opening, which
is three-quarters of an inch in diameter, will
have to be bored out in order to produce
a fine fit. The opposite end of a three-
eighths inch shank is turned and threaded
with a No. 40 thread, and this is done on
the lathe, as it is very difficult to obtain a
die with this pitch, unless made to order.
A double-concave lens three-quarters of
an inch in diameter is inserted in each tube.
These are firmly held in the seat by means
of a brass washer, made as shown in Fig.
19. A flannel ring with dimensions equal
to the metal washer should be inserted be-
tween the lens and telescope tube. Precau-
tion must be taken in securing the lens.
The lens can be procured at any opticians' shop at a nominal price. In purchasing the
lens it is advisable to obtain those having
a focal length of two inches, as this is the
proper size for the tube. One of these tubes is used for viewing, while the second
is used for admitting light to strike the
wire.

The wire or string is one of the most
difficult parts that the constructor will have
to obtain. This is a .002 mm. quartz fiber,
the surface of which is silver-plated. This
may be obtained from manufacturers of
scientific measuring instruments. They are
worth about $5.00 per string. However, if
the amateur finds it difficult in obtaining the
quartz, the writer has found that a No. 50
copper wire will give fairly good results.
The difficulty with this wire is that its tem-
perature coefficient is high in comparison
with the quartz, and it requires constant
adjustment with temperature changes. A
piece of No. 18 wire is soldered to each
end of the fine wires, so as to support it
between the stationary and movable holders
on the instrument. The tension is derived
by turning the top tension knob.

As soon as the constructor has made all
of the required parts, he should carefully
assemble them as indicated in Fig. 4. Great
care should be exercised to see that all parts
fit properly, as the sensitivity of the whole
device depends upon how accurately it is
made. Three binding posts are placed in
the rear of the base, those at the end are
connected to each of the electro-magnets,
while the central post is used to connect
the series terminals of the coils. Two
binding posts are stationed in the front
two holes of the base and these are used
to terminate the ends of the fine quartz or
copper wire. This is done by connecting
one terminal with the wire support,
while the second is brought from the Bakelite
insulating block screw, which has the lug with the
solid flexible con-
ductor. All of the
wires should be sol-
dered at all termin-
als so as to avoid
excess resistances,
as the currents travel-
 ing thru the quartz
or copper wire are
extremely minute in
magnitude, and a
slight increase in
contact resistance
would cause a sud-
den drop in ampli-
tude, which would
destroy the desired
effect.

Great care must be
taken in adjusting
and the following
points will be found to give excellent
results in adjusting the instrument as
found by the author from actual experi-
ence. First, the in-
strument should be
connected as indi-
cated in Fig. 20 for
adjustment. The two
cells are connected
in series with a six-
olt storage battery, B, an ammeter, A,
and a variable re-
sistance, R. The
string circuit has its
terminals 2, 2, con-
ected to a variable
high resistance R, with a maximum
range of 10,000

oms and a very sensitive milliamper-
eter M.A. A key, K, is inserted in the

Circuit and the maximum resistance is
inserted at the beginning of the test. Hav-
ing done this, the next thing is to see
whether the string will be displaced when
the current from the battery, B, is sent
thru it, and maximum exciting current
traveling thru the electro-magnet. This is
noted by viewing thru one of the tele-
scopes, while the other one is placed in
the path of a strong ray of light and intermit-
tently closing the key with a light tension
on the string. If the string does not de-
fect the trouble lies with the improper
connections of the electro-magnets giving
two like polarities at their pole piece, poor
electrical connections, or an open-circuit.
This should be remedied by carefully trac-
ing out the circuits. The former trouble
can be overcome by testing the polarity of
the pole pieces with the aid of a magnetic
compass. If the trouble lies with the pol-
arity, then reverse the leads from one of the
electro-magnets.

To adjust to maximum sensitivity, pro-
ceed as follows: Close the string circuit
key and adjust its resistance controller R,
until the milliamperemeter reads nine-hun-
dredths of a milliampere. Then obtain a
projector lens and place it in such a posi-
tion that if a beam of light from an in-
candescent lamp is placed before one of the
telescopic tubes, that the string will be
projected upon a white screen placed one
meter away from the instrument. Adjust
the lens so as to obtain a sharp image of
the string on the screen. At the point of
the string image, place thereon a metric
system rule with its millimeter scale facing
the string, and place so that the unit mark
shall accurately coincide with the string
image. Having all this performed, the next
step is to slightly tighten the tension of the
string, and with a minimum excitation cur-
rent in the magnet field, close and open the
key rapidly, and note the amount of de-
flection of the string image on the scale.

In order to detect when the gal-
vanometer is most sensitive, the string
must be displaced one millimeter on the
scale with the original predetermined cur-

(Continued on page 425)
Spectroscopic Methods and Spectra

A SEQUEL TO "HOW TO BUILD A SPECTROSCOPE."

By D. S. BINNINGTON

BEFORE taking up the production of Spectra, it will be necessary to refer back to the previous article on this subject—"How to Build a Spectroscope," which appeared in the August issue. The instrument described will perform a considerable amount of this work, but if this work is taken up systematically, as this kind of work should be, a few small additions to the instrument already described will be found convenient.

The chief of these is connected with the observation of the spectrum, namely the Telescope. The Spectrum can be observed by placing a reading glass against the spy-hole, which will magnify the spectrum sufficiently for general purposes, but for thorough work and good results a small telescope is a decided improvement. This need not be elaborate or expensive, and does not need to be very powerful, one magnifying about 5 to 7 diameters and costing about one dollar, is very satisfactory.

The mounting of this telescope is shown in Fig. 1. The block of wood is adjusted so as to bring the lens of the telescope on a level with the spy-hole, which must be enlarged sideways to allow of the telescope being moved. The telescope is fastened to this block by means of a strip of tin or copper, and the end of the telescope placed just inside the box which covers the prism, and exactly horizontal with the prism.

The exact angle between the prism and the collimator and telescope can only be secured by moving the prism till the maximum spectrum is obtained. The block to which the telescope is fastened should be fastened to the base by one screw only, so as to allow it to be moved sideways as all the spectrum cannot be seen at once. If this addition of a telescope to the instrument is made, the instrument will need to be adjusted.

This is done as follows: Place a small mirror in place of the prism, so that any light past into the collimator is reflected into the telescope. Having previously focussed the telescope on some distant object, place a white light in front of the slit, and slide the tube containing the slit (either in or out) till a distinct and clear image of the slit is seen in the telescope. Both the collimator and the telescope tubes should be marked with a line so that the instrument can be placed at these points when necessary. It should be noticed here that the collimator should not be moved from this position, but the telescope will need to be re-focused for each individual test in order to make the spectrum distinct and clear. If these directions have been followed carefully the instrument will be ready for use.

It would not be out of place here now to consider a little of the theory of the instrument, as this, if intelligently studied, will give the operator much more confidence in himself and a better understanding of the principles which underly the instrument. To do this, it will be necessary to go back to one of the first principles of Optics, which is that light of any description, when passing from a rarer to a denser medium, does not travel in a straight line but is bent at an angle out of its path, i.e., it is said to be "REFRACTED." This is easily seen from Fig. 2.

Now, light (by this is meant a primary color) has a definite wave length, by which is meant the length of the vibration of the ether which corresponds to the sensation of a definite color. In this respect, Red has the shortest wave length, and the other colors gradually increasing in wave length till violet is reached, which possesses the longest wave length of the visible spectrum. Beyond this, rays of still higher wave length, invisible to the eye, are known to exist. These are the ULTRA-VIOLET RAYS. The same is also true of the red end of the spectrum, in which waves of still shorter wave length than the red are known to exist. These are the INFRA-RED RAYS.

It will be useful to note here that the red rays are the heat-carrying rays, while the violet rays are the rays which produce chemical action, photography being due to the violet or Actinic rays.

From the fact that these colors which make up white light each have a definite wave length, it can easily be seen that they are not all refracted alike. This is actually the case, and can be readily demonstrated by holding a reading glass outside its focus on a sheet of white paper. A colored halo will be seen around the edge. This is due to the varying refraction of the light, which is partially split up. When a prism is used in this fashion, the effect is intensified and a spectrum results.

SPECTRA are divided into two classes, (1) Spectra in which the colors form a continuous blend. This is a CONTINUOUS SPECTRUM, and is produced by incandescent solids such as the particles of carbon in oil or gas flames, or the filament of electric light. See Fig. 1-A. (2) Spectra in which the colors are isolated bands. This is BAND-SPECTRA, and is produced by an incandescent VAPOR OR GAS. In the following material, whenever a white light, or a continuous spectrum is needed, either gas (an ordinary burner or Welsbach), oil or electric light may be used. When a colorless flame is mentioned, a Bunsen burner is preferable, but an alcohol lamp with a clean wick can be used.

The methods of producing spectra: Class 1. Methods in which gas, alcohol or gasoline is used to produce the spectra. Class 2. Methods in which electricity is used to produce the spectra.
ELECTRICAL EXPERIMENTER

Class 1 being the simplest will be taken up first. When using this method, however, it must be borne in mind that only those metals whose salts can be volatilized at the temperature of the Bunsen flame can be used for this method. The exceptions are Sodium, Potassium, Barium, Strontium and Calcium, and the rarer metals, Rubidium and Caesium, and the extremely rare metals, Thallium, Indium and Gallium.

The wires used in this method are preferably of platinum, but a pure grade of iron wire (piano wire) can be used satisfactorily if platinum is used, about 2 inches of No. 28 B. & S. gage is sufficient for each wire, but if iron is used about 3 to 4 inches of a slightly thicker wire should be used. The wires are mounted as shown in Fig. 3. A piece of glass tubing about 4 inches long and 3/16 diameter is drawn out to a jet, which, when heated off and the wire inserted, the glass tube is now heated around the wire till it fuses onto it. The other end of the tube is heated in a flame till it closes. The free end of the wire is bent into a loop about 1/4 inch diameter. If platinum wire is used, two wires will be sufficient, but if iron is used about six should be made. Platinum wires are kept in a small bottle containing chemically pure hydrochloric acid. The glass handle of the wire should be pushed thru a hole in the cork. They are cleaned by first wiping off any loose matter with a piece of cloth and then dip in hydrochloric acid and heated in the flame. This is repeated till no color is given to the flame.

If much work is planned, a stand to hold these wires when in use is desirable. This can be made easily as follows: Make a base of wood, about 2 inches square and 1/2 inch thick. Thru the center bore a small hole, the width of which is about a stiff pointed piece of steel wire (a hatpin with the head removed is just the thing). Then take a cork about 1 inch long, and push it on to the pin so that it can be moved but fits tightly. Bore a small hole in it to take the glass handle of the wire at right angles to the upright pin. The wire can then be moved up and down or around, and adjusted and held in the flame for any required length of time without any trouble. The finished stand is shown in Fig. 4.

The Spectrum is taken by this method as follows: First take a white light, and place it in front of the slit and about 12 inches away. Observe the spectrum and gradually move the lamp closer till a point is found at which the maximum intensity of the spectrum is obtained. This point is noted and always used in practice. It would be as well, however, to note that lamps of different electrical methods vary in intensity of illumination and the writer advises determining experimentally the most efficient working distance for each method. When this distance has been obtained, the thoroly cleaned wire is moistened with hydrochloric acid, dipped in the powdered salt, placed into the holder and heated in the flame. If much work is being done, it is advisable to darken the room, as this is easier on the eye.

When a spectrum is wanted for a considerable length of time, the following procedure can be adopted:—A small piece of asbestos wool is placed in a large test tube, covered with hydrochloric acid, and boiled; the acid is then decanted off, water added, shaken up well, the asbestos allowed to settle, and the water decanted off. The asbestos is then shaken out onto a piece of cheese-cloth, squeezed till dry, placed in the tube again, fresh acid added, and the process repeated. It should then be held in a twist of wire and heated in the flame for about 5 to 10 minutes. If it colors it at the end of this time, it should be again washed with acid and water. When clean it is twisted onto a clean wire about 5 to 6 inches long.

The material desired for the spectrum is dissolved in water to make a strong solution. The asbestos is dipped into this, and then gently heated till dry, and then again dipped into the solution and re-dried. Two drops of hydrochloric acid are dropped onto it and it is heated in the flame. The spectrum thus produced will last a considerable time.

This method has one objection, however, and that is, when the asbestos becomes red hot, it gives a continuous spectrum, but if the slit has been made narrow enough this will not cause any trouble.

Occasionally, a yellow sodium light is required. This can easiest be made by using an alcohol lamp and placing a little salt, or borax, into it. This will give a yellow light indefinitely.

The best salts to use in taking flame spectra are the chlorides or chlorates. If these cannot be obtained, however, the available salt is mixt to a thick paste with hydrochloric acid. This subject, however, will be examined in further detail. This about covers the field of one method of spectra-production. The next section to be taken up is:

ELECTRICAL METHODS

Electrical methods can be sub-divided into three general classes:—

(1) Production of spectra of and in gases.

(2) Production of spectra of liquids or solutions.

(3) Production of spectra of solids.

Class No. 2 being the one most widely applied, will be considered first. In this method the materials in the form of a solution is vaporized in the electric spark.

The apparatus requires an induction coil, giving not less than 1/2 inch spark. Indeed the larger the spark the better will the results obtained. The apparatus is shown in detail in Fig. 5. The glass cup "A" should be about 1 diameter and about 3 inches long. Test tubes can be purchased about 8" x 1", which when treated as before, make two excellent cups. The tube is cut out about 3/4 down. This gives one good cup about 3" long and a piece of tube about 5" long. It is heated in the flame and worked with a large nail till the bottom is closed. This will eventually bring it to about the same length as the other.

Of course as will be seen later on, a small jet 1/2" or 1/4" is correct. This will be used, but the author would not advise this as the thickness of the glass will cut off some of the violet rays, besides distorting the image, which the apparatus made with a test tube is easier to make and will give far more satisfactory results.

A hole about 3/16" in one end now be made into the bottom of the tube. This is done as follows:—Plug up the tube with a cork thru which passes a piece of glass tubing connected to the side arrangement with a piece of rubber tubing. Heat about 3/4" in the center of the bottom of the cup with a small flame, to bright redness, and then blow thru it, so that it will then blow out. It should be carefully trimmed with a file till it is flush with the tube. The edges of this hole should now be heated in a small mouth-blowlip flame till they fuse and assume a smooth appearance.

The next step requires about 3" of platinum wire. This can be obtained from any laboratory supply house. A six-inch piece of No. 28 is about right. Add about 75c and will make various pieces of apparatus, No. 32 B. & S. can be used and comes a little cheaper, but No. 28 is more satisfactory and will give better service.

The tube "B" is about 5 inches long and 3/16" internal bore. One end has sealed into it, about 1 inch of platinum wire, so that about 1/4" projects into tube. The tube "C" is the most important part of the apparatus, and the directions should be carefully followed. A piece of glass tubing about 1/2" internal diameter is drawn out to a jet and cut off to about 1 inch over-all length. The large open end of the tube is pointed in the flame, and the jet end is ground on a piece of moist emery cloth till it has an aperture not larger than 3/64" (between No. 28 and 30). The bottom of this tube is corked with a small piece of rubber thru which a small hole has been made. Thru this hole, the platinum wire (about two inches) is worked, so that when the rubber stopper is in place, the platinum wire is just in the end of the jet. The position of this wire can always be adjusted by moving the rubber stopper slightly. About 1/4 inch or more of wire should project beyond the lower end of the valve, and the bottom of the tube is then drawn into the tube "A" by a cork in the lower hole. The tube "B" is fastened into the tube by a large cork, which should have a slit cut in one side to allow gases to escape. The distance between the spark (Continued on page 427)
Ohm’s Law and A. C. Circuits

By ARNO A. KLUGE, Instructor in Radio, University of Nebraska

A SUBJECT that is usually rather hazy in the mind of the practical electrical man who has never had the opportunity of engineering training, is the application of Ohm’s law to alternating current circuits. This may be traced to a total lack of literature of a concise nature on the matter, for in most text-books it is necessary to digest several chapters of non-essentials before the point is reached.

In alternating current practise we encounter three different kinds of paths or conductors of the current, and it is the method of computing their effective resistances in various combinations that this article has to deal with. The first kind is the simple straight wire, whose resistance, for low frequencies, at least, depends wholly upon its length, cross-section, and material. It must be clearly understood that this applies only to currents of audio frequencies, as from 25 to 500 cycles, since any conductor at audio frequencies possesses appreciable capacity and inductance.

The second and third cases of paths are the condenser and the inductance coil, designated as capacity and inductance, respectively. Seldom if ever do we find these cases in a circuit alone, but usually in combination with one or both of the other two. For example, an inductance coil always has resistance associated with it, since it is impossible to obtain a perfect conductor.

We can then make a table for the equivalent ohmic resistance of each of these types, from the data we find in text-books, as follows:

<table>
<thead>
<tr>
<th>Type</th>
<th>Equivalent Ohmic Resistance</th>
<th>Simple</th>
<th>Resistance of conductor</th>
<th>[ \frac{1}{C} ]</th>
</tr>
</thead>
<tbody>
<tr>
<td>R</td>
<td>(Resistance of conductor)</td>
<td>[ \frac{1}{R} ]</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C</td>
<td>(Capacity in farads)</td>
<td>[ \frac{1}{C} ]</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Inductance, \( L \), (\( L = \) inductance in henries) in the above \( P \) represents the reactance factor of the current applied, being \( P = 2\pi f \) (where \( f \) = frequency in cycles).

The difference in the value of these resistances is due to the differing effect which they have upon the voltage and current of our power supply. A condenser in the circuit, and by use of the formulae attached the student is enabled to calculate the current which will flow in any possible circuit. It should be borne in mind, however, that while these formulae will give the actual value of the current flowing in the circuit, we cannot then multiply this amperage by the impressed E.M.F. and obtain the power consumption of the circuit in watts. The latter is wholly dependent upon the power factor, i.e., the per cent lag or lead of the current, and it will be necessary to multiply the product by this factor to obtain the true wattage consumption of our circuit.

The power factor of an A. C. circuit is found by dividing the true watts as read off from a compensated indicating watt-meter by the apparent watts, which latter term is the voltage resultant from multiplying the effective or indicated volts by the effective or indicated (or calculated) amperes. Some A. C. installations are fitted with a direct reading power factor meter.

WOMEN INSTRUCT IN RADIO WORK.

Miss Baruch, daughter of Bernard Baruch of Glen Cove, Miss Chanler of Stony Brook and Miss Ferrine of New York are instructing the men of the air service at Mitchel Field in radio work. There are twenty-five other women who are volunteering their services in instructing the men in both the English and French language. Special attention is given to the men who are not familiar with the English language, with especial reference to military terms.

At one period no mail reached the miners of Spitzbergen for eight months, but they are now able to get the world’s news twice a day by wireless telegraph.
The Manipulation of Glass Tubing in the Experimental Laboratory

By Prof. HERBERT E. METCALF

Part II

It is often necessary to fuse a small tube to a large one or to make other end-to-end fusions. Fusions are the hardest part of glass-blowing and must be done carefully in order to produce satisfactory results. Many experimenters heat the ends of two pieces of glass in a flame and then stick them together only to find out that they will break apart upon the least provocation. A real fusion, properly done, will prove as strong as any other portion of the tubing. Heating the ends and sticking them together is the first part of the process, it is true, but the procedure extends beyond that. After the ends are stuck together they must never be allowed to cool. A cork is stuck in one of the ends and then a sharp needle-like flame from the bunsen lamp is directed at one side at the place where the two tubes join. This point will soon become white hot, the glass will run together and will bend in under the force of the flame. Removing the flame, blow very gently into the open end of the tube, thus bringing back the bent portion into its proper shape. At this point the glass is properly fused. This same procedure must be repeated all around the circumference of the fusion. When finished all points will be perfectly fused, with the two ends of each melted off smoothly one into the other. All this time the tube must not be allowed to cool. Therefore the work must be done rapidly and the joint must not be laid down until entirely finished. When the fusion is completed it must be gradually cooled in a yellow flame until sooted. It may then be laid on the asbestos mat to cool.

Making "T’s" and "Y’s"

T’s and Y’s are only variations of the end-to-end fusion process. The principal difference, however, is in making the hole in the side of the glass tube, and the order of procedure in the more complicated pieces.

To make a hole in the side of a piece of glass tubing is a simple matter, but to make a hole of the proper size is much more difficult. First select the top bar of the "T" and direct a sharp, very fine needle-pointed flame, at the place where the hole is to be, see Fig. 5. A cork has been placed in one end of the tube will enable the manipulator to blow out a small bubble on the side of the tube at the point which the blow pipe is heating white hot. Now the size of the resultant bubble will depend upon the area which is white hot and also upon the force with which the bubble is blown out. A few trials will soon give the knack of obtaining various sizes of holes. This bubble may then be broken with a file and the edges trimmed down, taking extreme care to leave a small lip to aid in fusion. The hole is now ready for the fusion. Heat the edges of the hole until they are sticky; heat the end of the piece to be fused on until it also is sticky, then stick them together with a slight rotary motion, being sure that no small air leak exists. If a leak is present it will prevent the effect of blowing in the tube.

As there are now two open ends, one of them must be plugged with a cork, leaving only one to blow into. The needle pointed flame is again brought into use and the joint fused by alternately melting in and blowing out the glass all around the circumference of the weld. The "T" must then be sooted thoroughly and laid away to cool.

A few words about this all important blowing operation which forms a part of all glass tubing manipulation. It is so important it must be thoroughly understood. Upon directing the needle-pointed flame on a portion of the circumference of two tubes at the point where fusion is to take place, the flame, depending on the size of the flame, will become white hot and the edges will fuse or run together. But, at the same time the tube at this point will bend inward, and must be gotten back into shape. This is done by blowing gently into the open end of the tube just hard enough to get the hot por-

Duplicating a Commercial Glass Vacuum Pump (left) by Simple Home-Made Design (right). Former cost $2.50—"Made in Germany." Latter cost 25 cents and works just as well.

Having made a "T" it is a very simple matter to make a "Y". After the "T" has been fused, direct a larger flame so as to heat the entire tube in the neighborhood of the joint and then bend into the shape of a "Y".

Tubes with any number of side openings may be made: A cross may be made with one precaution. Proceed to make a "T" and then immediately start working on the other side without allowing the first joint to cool. This is to avoid re-heating and re-cooling a joint once made, as they are apt to crack.

Making Constructions in Glass Tubing

The ordinary way of making a constriction in a glass tube is to merely heat a portion of the tube and then draw the two ends apart until the required result is obtained.

(Continued on page 422)
An electric furnace is an apparatus for the production of high temperature by electricity. The advantages of such an apparatus are—the direct application of heat to the material, thus eliminating excessive losses by conduction thru the walls of a containing vessel; the production of high temperature, usually above those obtainable from fuel in common uses; simple and accurate regulation, giving absolute control of a process and an economical use of power; and finally, with sources of water-power, a low operating cost.

There are several types of electric furnaces in use. The general division are—the Induction type, and the Resistance type. The purpose of this article is to give the experimenter the simple construction details and operating principles of these furnaces.

Before going further, it is well to inform the operator of any of these devices to watch his fuses, as many will be blown without the proper regulation of the rheostat in Fig. 1. The experimenter will find that a transformer is not necessary for a small arc furnace, but in the case of the resistance or induction types a higher voltage than the ordinary lighting current is required for good results.

The author has found the simplest rheostat to be of the water-barrel type. A wooden spool is first filled with strong salt water. A metal plate in the bottom is attached to one lead, which is well insulated; a piece of rubber hose over the wire is excellent. To this other lead is soldered a metal electrode of any sort. The distance between the plate and the electrode regulates the current; the closer they are the less the resistance. The experimenter may fit up a support for his adjustable electrode to suit his convenience. Fig. 2.

The arc furnace is by far the best for the amateur. It is the simplest and cheapest in construction, the easiest of operation and regulation, the most economical and is productive of higher temperature than the other types.

A furnace which will give practical results can be made from two blocks of slaked lime, hollowed out and grooved for two carbon electrodes, as shown. This apparatus, with proper lighting current, is the same as an arc-light. To start the arc in operation the carbons are touched together and then drawn a small distance apart, giving a steady arc. The material to be melted is placed in the hollow beneath the arc. To stop the arc, the carbons are drawn far apart, thus breaking the arc. The use of a rheostat or "ballast" improves the steadiness of the arc. A transformer is not necessary as was stated before.

As an electric arc between carbon wears down the positive electrode, adjustment is frequently necessary in order to maintain the flow of current. One carbon...
furnace, the amperage varying with the resistance offered by the material. The carbonodeum furnace at Niagara Falls runs on potentials as high as 22,000 volts.

The induction furnace (Fig. 8) is not a practical one for the experimenter. It requires some of the circuit material to start it, and due to the high reactance resulting from the distance between the primary and

secondary is uneconomical for a laboratory device. The induction furnace operates as a transformer, the secondary winding in this case being the "charge," which is contained in the circular channel A, and is heated by the secondary current. The amount of energy put into the secondary can be varied by varying the applied primary voltage.

It is hoped that these few notes will prove useful to the electrical experimenter. There is a large number of unsolved problems connected with the behavior of various substances at high temperatures yet to be worked out, and the results of some experimenter's research may be, for all we can tell, of great commercial or scientific value.

TRICKS IN 3- AND 4-WAY LIGHT SWITCHING.

By Y. R. MANN

In the experimenter's laboratory it is often desirable to control the flow of current from two or more points. To accomplish this easily and at a low cost, battery type, porcelain base, knife switches may be substituted for the 3-way and 4-way push button switches. It must be remembered, however, that when the current is turned off by opening one of these switches (see Fig. 1) the blade must be thrown over to the opposite contact, so that the throwing of another blade will close the circuit again. In the standard snap and flush switches this operation is accomplished automatically by means of the spring.

The solid lines from switch to switch (Fig. 1) show the circuit as arranged for control from three points, using one double-pole and two single-pole, double-throw switches. The connections for control from two points are made by using only the single-pole switches, connected to the line and load as shown, and connected together as shown by the dotted lines.

Making a D. P. Switch from a 3-Way.—Any standard 3-way flush push-button switch may be changed to a double-pole switch by removing the contacts from one side (not one end) of the shell and transposing them. As in a 3-way push-button switch, the contacts are arranged so that there is a high and a low one in each end of the shell, this change gives two high contacts in one end and two low ones in the other, making the switch either all on or all off at each consecutive push.

The strip of metal which bridges the "live" contact of the 3-way must be removed or permanently disconnected. Line connection may be made to the point which has no screw by soldering the wire to it or by simply hooking the wire firmly and tightly in the unthreaded hole.

To change a double-pole flush push-button switch to a 3-way, reverse the above operation, bridging one end by a piece of wire and removing one screw from that end so that the "live" end can be readily distinguished.

3-Way Hook-Ups.—Fig. 2 shows two S. P. D. T. knife switches connected up to control two lamps in two rooms from two different locations. Fig. 3 illustrates two 3-way (or two S. P. D. T. knife switches) controlling two or more lamps, A, B, etc., in a group, the switches being placed in such positions as at the top and bottom of a stairway, etc.

FILING SMALL HOLES.

It is often necessary to enlarge a hole thru a thick piece of metal by filing. If a very thin file is used, that will pass right thru the hole, there will be no risk of its getting jammed and snapping off with the end firmly imbedded in the work, as might happen if a stouter file were used that would only enter the hole for a portion of its length. On the other hand, only a limited amount of force can be exercised with safety when using a thin and delicate file, which makes the operation rather tedious.

The best way is to select as strong as file as possible for the job, marking the safe limit to which it may enter the hole, and preventing it from going any farther by slipping a small clinch or circlip at the end. The file can then be used vigorously without any risk of striking.

Contributed by H. J. GRAY.

AN EXTENSION GONG FOR A CLOCK.

In the sketch, A is a carbon cup holding mercury; B, a piece of No. 10 gage wire; C, a weak spring to raise B from cup; D, stop to prevent apparatus from turning out of position; E, piece of tin cut in triangular shape; F, pivot for tin triangle; G, cord or catgut connecting hammer with triangle; H, hammer, and I, the clock gong, as might happen if a stouter file were used that would only enter the hole for a portion of its length. On the other hand, only a limited amount of force can be exercised with safety when using a thin and delicate file, which makes the operation rather tedious.

The best way is to select as strong as file as possible for the job, marking the safe limit to which it may enter the hole, and preventing it from going any farther by slipping a small clinch or circlip at the end. The file can then be used vigorously without any risk of striking.

Contributed by H. J. GRAY.

A "Mercury Switch" Rigged Up to Ring Extension Bells Whenever a Clock Strikes the Hour and Intermediate Periods.

I recently made an extension electric gong for a clock, so that it would strike whenever the clock struck, but I experienced trouble in getting good contacts in the clock. At first the contact was made by the hammer striking the gong, but this did not give satisfaction, so I devised an apparatus which is shown in diagrams, that worked with excellent success.

The carbon cup, A—which is mentioned in the diagrams—is easily made from a piece of a round carbon from an old battery. The holes are easily made in it with the use of an old pocket knife.

TITLING BOOKS

Many readers desire to title bound volumes of the Electrical Experimenter, or other magazines, or books which have been re-covered, etc. The usual method is to mark it in either black or white ink, according to the color of the covering. This method may be improved upon by applying a coat of transparent shellac over the lettering, and thus prevent the wording from becoming obliterated from hard usage or by being rubbed off with the fingers. When the lettering his dried, the shellac is applied, and allowed to dry thoroughly before being used. It is advisable to apply one or more coats to the cover.

Contributed by ALBERT W. WILSDON.
Chlorin was first prepared by Scheele in 1774 while he was experimenting with "black magnesia" (an ore consisting largely of manganese dioxide) and hydrochloric acid, but it was not until 1801 that Davy first established its elementary character. Scheele called it "Dephlogistic Muriatic Acid". Berthollet named it "Chlorated Muriatic Acid", supposing it to be a compound, because he observed that its solution in water yielded muriatic (hydrochloric) acid and oxygen, when placed in sunlight. Davy applied the present name, chlorin, on account of its greenish-yellow color.

Gay-Lussac and Thenard demonstrated that one volume of it united with one volume of hydrogen to form hydrochloric acid.

OCCURRENCE.

Chlorin does not occur in the free state in nature as its affinities are too great. It is found abundantly in combination with sodium in the form of sodium chlorid, which is found in sea waters, inland lakes, and beds of deposite, from which it is dug like coal. It is also found combined with magnesium, which is a much smaller constituent of sea water than sodium, and which is also found in some mineral springs.

Preparation.—(1) In the laboratory it is usually prepared by removing the hydrogen from hydrochloric acid with the aid of manganese dioxide. In this reaction the hydrogen taken from the acid unites with the oxygen of the manganese dioxide, according to the equation:

\[ 4\text{HCl} + \text{MnO}_2 = \text{MnCl}_2 + 2\text{H}_2\text{O} + \text{Cl}_2 \]

Chlorin has affinity for metals, and so half of it unites with the manganese present to form the compound manganous chlorid (MnCl). It might be expected that MnCl + 2H₂O would be the products, but one atom of manganese cannot hold more than two atoms of chlorine, and half the chlorin is thus set free, having nothing with which to combine, while all the oxygen goes to form water. You will observe that the valence of the manganese in the factors (to the left of the above equation) is 4, while in the products (to the right of the above equation), it is 2; or in other words, towards oxygen, manganese has a valence of 4, while towards chlorin its valence is 2. This is a reduction and oxidation, hydrochloric acid being the reducing agent, manganous chlorid the reduction product, and chlorin the oxidation product.

(2) It may be prepared by the electrolysis of hydrochloric acid or the chlorides by utilizing the electrolytic generator shown by Fig. 130 of this series, in the September issue of this journal. The principle involved is the decomposition of the acid, or chlorides, by means of an electric current, in which the chlorin is liberated and collected at the anode, and the hydrogen or sodium (if sodium chlorid is used) collected at the cathode. In the various processes, many mechanical difficulties have been encountered in the form of secondary reactions taking place with the formation of sodium hypochlorit, chlorat and chlorid, due to the diffusion of the chlorin thru the solution, the reactions being:

\[ 2\text{NaCl} = \text{Na}_2 + \text{Cl}_2 \]

\[ 2\text{NaCl} + \text{Cl}_2 = \text{NaClO} + \text{NaCl} + \text{H}_2 \]

\[ 3\text{NaClO} = \text{NaClO}_3 + 2\text{NaCl} \]

\[ \text{Na}_3 + \text{H}_2\text{O} = 2\text{NaOH} + \text{H}_2 \]

Numerous devices have been invented to overcome this difficulty. Probably the most successful has been the Castner-Kelner process, described in the November, 1917, issue and illustrated by Fig. 88 of the same issue.

(3) On the large scale chlorin is made by a method known as the Weldon process. The only difference between this method and the one first described above, namely that of acting on manganese dioxide with hydrochloric acid, consists in transforming the manganous chlorid into a compound that can be again treated with hydrochloric acid. The manganous chlorid was formerly wasted, and thus the cost of chlorin, when made into bleaching powders, etc., was considerable, caused by the necessity of using new manganese dioxide each time. By Weldon's method the manganous chlorid obtained is treated with calcium hydroxid (slaked lime, Ca(OH)₂), converting it into manganese dioxide, thus:

\[ \text{MnCl}_2 + \text{Ca(OH)}_2 = \text{CaCl}_2 + \text{Mn(OH)}_2 \]

A SIMPLE BATTERY MOTOR FOR THE BOYS.
I am sending you a plan of an electric motor which I designed. The rotor is made of an old spool such as magnet wire comes on. On its circumference are set eight nails or screws on either side of the spool and these spaced evenly apart. One set of screws or nails is used for the commutator as shown in Fig. 2. This set of screws is connected to the shaft by wires as shown. When the screw D comes to brush E, F is drawn to the coil and on. The connections are as follows: One terminal of battery is connected to the shaft by means of a brush, or by connecting a wire to the frame. The other terminal is connected to one side of coils, and the other terminal of coils is connected to brush E, Fig. 2.

HOW TO OIL KNIFE SWITCHES.
As oil is an insulator, it cannot be successfully used to make switches work easily of the ordinary blade and clip type, as the oil forms a film between the switch-post and switch-blade, thereby insulating one from the other. This may be overcome in the following manner:
To the switch-post solder one end of a flexible conductor about two or three inches long. Solder the other end to the switch-blade. For this conductor drop-cord for electric lights will serve very efficiently.
Contributed by RICHARD J. ANDERSON.

AN ELECTRIC “COMBINATION” DOOR LOCK.
The sketch shows a simple electric door lock attachment which any amateur electrician can make. It has been in use on my door for several months and has proven entirely satisfactory.
The solenoid “S,” armature “A,” and hook “B” are mounted on the casing of the door; inside the house of course. The row of push buttons “H” is placed outside of the door. The buttons 3, 4, and 6 are connected in series with the relay switch “I,” which is normally closed, and the solenoid coil “S.” Buttons, 1, 2, 5, and 7 are connected in multiple and the group in series with the relay switch magnet “D.”
If buttons 3, 4 and 6 are prest, coil “S” is energized, raising the hook “B” which allows the door to be opened. However, if any other buttons are prest at the same time, then coil “D” opens the solenoid circuit at “P,” and the door remains fastened. “C” is a switch placed inside the room to open the door when leaving or to admit anyone.
Contributed by RAE GALUSHA.

BURGLAR ALARM FOR A SLIDING DOOR.
This alarm has worked with success and I thought that someone else might wish to use it. The material consists of a strip of brass, a screen door spring, a long nail, an electric bell, switch and batteries. Fasten the strip of brass at one end on wall and bend it to shape shown in diagram. Drive nail in ceiling so that strip of brass will hit it when the door is open. Then fasten screen door spring so it will pull the brass strip against the nail “A,” when the door is shut the brass strip is held away from the nail, but when it is open the brass strip touches the nail and closes the circuit, causing the bell to ring.

Every Trade Needed To

EUROPE is devastated. It must be rebuilt. And America must rebuild it. American brains, ingenuity, and inventive genius are going to supply war-torn Europe with new buildings, new factories, new machinery, new equipment of every description. In fact, there isn’t one thing needed in the reconstruction of Europe that America won’t supply. Can you grasp what that means?

The moment peace is declared America will begin the titanic task. No other country can do it. Think of what it will mean to America—to YOU and every ABLE man in the country. The task facing America will mean a decade or more of unparalleled prosperity—an era of COLOSSAL OPPORTUNITY for the TRAINED MAN. Earning power will be limited only by the lack of ability to DO THINGS. Every line of business will be worked to the limit. There can be no question about that, for the skilled workers of Europe have died by the hundreds of thousands. Now you see why training is so essential, and why every man not in the fighting line must prepare for the gigantic task facing America. The man with TRAINING will reap rich rewards.

Prepare Now For the Big Future

Don’t sit on the sidelines when the big call for trained men comes. You don’t have to. TRAIN and get into the game yourself. In six months you will be better fitted for the job you want than you are now. In a year you will have a strong grip on that job. In two years you can be an expert—a big money-maker. There will be a place for you no matter what your profession or age may be. There is time for you to get ready if you begin NOW. Trained men will be capable of earning salaries that will satisfy the most ambitious. And there will be a hundred or more openings for every man who can deliver the goods. There is no limit to the opportunities facing YOU and every man in the U. S.—only the limit you place on yourself.

Results Follow If Training Leads

It needs a little backbone to study. It means devoting some part of your leisure hours to learning. But if you are man enough to do it, then the rewards are so sure—so certain—that the time you spend in home study will repay you a thousandfold. There is going to be a tidal wave of prosperity sweeping this country. It is beyond dispute. Are YOU going to ride on the crest of it, or will you be content to travel with the driftwood that follows it? IT IS UP TO YOU!
Train with the Greatest Educational Institution in America

If you have ambition, and the backbone, you are going to prepare for the immense possibilities of the near future. It is simply a matter of saying "I WILL" and mailing the coupon below. No matter what profession you choose to follow, you will have back of you the greatest correspondence school in the country—the greatest staff of experts in all branches of endeavor to instruct and coach you. Back of this staff, back of this great institution, is nearly twenty-five years' experience. The American School has the prestige of having trained thousands of men—and women—who today rank high in the industrial and commercial world. They have made their respective marks because they were TRAINED. But first they marked the COUPON.

Satisfaction Guaranteed One policy governs the American School: the student must be satisfied, or his money is refunded in full. There is no quibble or equivocation about it. Just as it is up to you to mark the Coupon to prepare for the golden age to come, so it is up to you to tell us if you are not satisfied. That guarantee goes with every Course. Then there is the EASY PAYMENT PLAN that makes it possible for you to get training without missing the money.

Mark and Mail Coupon In one of the Courses below lies your future—a big future if you master that Course. And you can do it without a doubt. On receipt of the coupon we will promptly send you full particulars—everything you will want to know about the Course you are interested in, the Instructors back of you, our business and training methods, Refund Guarantee and easy payment plan. Send the Coupon NOW—while this most important matter is before you.

Every Trade Needed To Rebuild Europe

EUROPE is devastated. It must be rebuilt. And America must rebuild it. American brains, ingenuity, and inventive genius are going to supply war-torn Europe with new buildings, new factories, new machinery, new equipment of every description. In fact, there isn't one thing needed in the reconstruction of Europe that America won't supply. Can you grasp what that means?

The moment peace is declared America will begin the titanic task. No other country can do it. Think of what it will mean to America—to YOU and every ABLE man in the country. The task facing America will mean a decade or more of unparalleled prosperity—an era of COLOSSAL OPPORTUNITY for the TRAINED MAN. Earning power will be limited only by the lack of ability to DO THINGS. Every line of business will be worked to the limit. There can be no question about that, for the skilled workers who have died by the hundreds of thousands. Now you see why training is so essential, and why every man not in the fighting line must prepare for the gigantic task facing America. The man with TRAINING will reap rich rewards.

Prepare Now For the Big Future

Don't sit on the sidelines when the big call for trained men comes. You don't have to. TRAIN and get into the game yourself. In six months you will be better fitted for the job you want than you are now. In a year you will have a strong grip on that job. In two years you can be an expert—a big money-maker. There will be a place for you no matter what your profession or age may be. There is time for you to get ready if you begin NOW. Trained men will be capable of earning salaries that will satisfy the most ambitious. And there will be a hundred or more openings for every man who can deliver the goods. There is no limit to the opportunities facing YOU and every man in the U.S.—only the limit you place on yourself.

Results Follow If Training Leads

It needs a little backbone to study. It means devoting some part of your leisure hours to learning. But if you are man enough to do it, then the rewards are so sure—to certain—that the time you spend in home study will repay you a thousandfold. There is going to be a tidal wave of prosperity sweeping this country. It is beyond dispute. Are YOU going to ride on the crest of it, or will you be content to travel with the driftwood that follows a? IT IS UP TO YOU!

Train with the Greatest Educational Institution in America

If you have ambition, and the backbone, you are going to prepare for the immense possibilities of the near future. It is simply a matter of saying "I WILL" and mailing the coupon below. No matter what profession you choose to follow, you will have back of you the greatest correspondence school in the country—the greatest staff of experts in all branches of endeavor to instruct and coach you. Back of this staff, back of this great institution, is nearly twenty-five years' experience. The American School has the prestige of having trained thousands of men—and women—who today rank high in the industrial and commercial world. They have made their respective marks because they were TRAINED. But first they marked the COUPON.

Satisfaction Guaranteed One policy governs the American School: the student must be satisfied or his money is refunded in full. There is no quibble or equivocation about it. Just as it is up to you to mail the Coupon to prepare for the golden age to come, so it is up to you to live up to your promise. That you can do is the basis of every course. Then there is the EASY PAYMENT PLAN that makes it possible for you to get training without missing the country.

Mark and Mail Coupon In one of the Courses below lies your future—a big future if you master that Course. And you can do it without a doubt. On receipt of the coupon we will promptly send you full particulars—everything you will want to know about the Course you are interested in, the training back of it, the curriculum, training methods, Refund Guarantee and easy payment plan. Send the Coupon NOW—while this most important matter is before you.

BOILING WATER WITH ICE.

This is an old, the very curious and interesting experiment, calculated to mystify the uninitiated.

Obtain a Florence flask or glass distilling retort and fill it half full of water. Boil the water, and immediately on removing the flame, cork the flask tightly, and turn it upside down. As soon as the steam condenses it will form a partial vacuum over the water. It is well known that water boils in a vacuum at a much lower temperature than is required in the open air, and consequently, if the vacuum could be kept up, the water would boil long after it was removed from the source of heat. But as soon as steam is formed, it exerts a pressure on the water and stops the boiling.

If now we place a piece of ice on the top of the flask, the vapor or steam will be condensed, a vacuum will be formed and the water will commence to boil violently and will continue to do so until the temperature of the water in the flask falls below that at which water boils in a vacuum.

If the ice be removed before this occurs, the vapor will again form, press on the water and stop the boiling; but the boiling may be renewed by replacing the ice.

In performing this experiment, it is well to wrap the ice in flannel to avoid the dripping of the melted ice.

Contributed by V. H. TODD.

A FEW USEFUL INK FORMULAS.

Blue ink:

3 parts Prussian blue.
1 part Oxalic acid.
30 parts water.

When dissolved add 1 part of gum arabic.

Green ink:
Sap green dissolved in very weak alum water.

A good ink eraser:

A. Oxalic acid mixed with citric acid may be used.
B. Equal parts of cream of tartar and citric acid in solution with water.

Inks that appear thru heat:

A. A weak solution of nitrat of copper; when heated it becomes (Red).
B. With a solution of sulfuric acid (Black).
C. With lemon, onion, leek, cabbage or milk and will be visible when paper is heated.

D. With a weak solution of nitrat of mercury (Black).

Invisible ink:

A. Write with pure dilute tincture of iron and develop with a blotter moistened with tar.
B. Linseed oil, 1 part
Ammonia, 20 parts
Water, 100 parts
Mix well before using.

Vanishing ink:
To make an ink black at the time but that will disappear in 24 hours: Boil nutgalls in alcohol, add copper sulfate and sal ammoniac, let cool and then dissolve a little gum in it.
Contributed by GEORGE JOHNSON.

HOW TO MAKE, USE, AND TEST COAL GAS.

A test tube is half filled with ground soft coal, packed loosely. The tube is heated and the gas allowed to pass thru a bottle filled with air. Anything left in this bottle will be coal tar. The gas is then past thru lime water. If any carbon dioxide is present, the lime water will become milky. The gas is then past thru the last jar containing red litmus solution. This will turn blue in the presence of ammonia. From the last bottle, the gas may be allowed to flow thru a rubber tube in the end of which is a burner. The gas will burn with a yellow flame. Using a 6" x 3/4" test tube, this flame will give about 1 candle-power.

Contributed by MORTON BERMANN.

"CHEMICAL SNOW."

Two parts Strontium Nitrat are first dissolved in 20 parts of water. Dissolve 2 parts Sodium Carbonat in 10 parts of water (heat may have to be used to dissolve it). Pour the second solution into the first. The result resembles a miniature snow storm. Sodium Carbonat and Strontium Nitrat react, forming Sodium Nitrat and Strontium Carbonat. The latter is not soluble in water.

"Pouring Red, White and Blue from the Same Pitcher": Fill 3 glasses 2/3 full of water. In the first dissolve 1 measure of Ammonium Sulfocyanat. In the second 1 measure of Strontium Nitrat and in the third 1/2 measure of Sodium Ferrocyanat. In the pitcher dissolve 3 measures of Ferric Ammonium Sulfat in 1/3 glassful of water. Pour a little of this into each glass. The first will turn red, the second white and the third blue.
Contributed by DUNBAR L. SHANKLIN.

SILVER-PLATING GLASS.

To silver-plated glass first have the glass clean. To clean it well wash it first with an alkali and then with distilled water.

Now dissolve 7.8 grammes of silver nitrat in 6 c.c. of water and divide the solution in two equal portions. Dissolve also 3.11 grammes of Rochelle salt in 1180 c.c. of water and heat the solution to the boiling point. Add to it gradually, so as not to stop the boiling, one of the portions of the silver solution, boil 10 minutes longer, cool and decant the clear liquid. To the other half of the silver solution add just sufficient ammonia water to dissolve the precipitat which is formed, or only leave a faint cloudiness; then add 350 c.c. of water and filter. Equal portions of these two solutions, when mixed and poured on glass, will deposit a brilliant coating of silver in about 10 minutes, depending on the temperature of the room.

The coating of silver should then be well washed, dried and varnished.
Contributed by WALTER SWANSON.

A SIMPLE RENEWABLE FUSE.

Amateurs utilizing large amounts of current usually have trouble with their fuses blowing out. A method that makes this occurrence less expensive is to make use of the so-called renewable fuses.

Cartridge fuses may easily be arranged so that new pieces of fuse wire may be put in very easily. A fuse of the proper size as regards the clips is obtained and the brass caps slit with a saw as shown in the illustration, thus cutting the ends of the caps into four pieces. The pointed ends are bent in and in this manner the caps are fastened permanently to the fiber tube. The asbestos filling is removed and the tube cleaned out.

To renew such a fuse it is only necessary to run a length of wire of the proper size thru the tube and bend the ends of the wire around the ends of the tube, thus making connection to the brass caps. When the fuse blows the melted metal will not spatter, since it is confined by the tube. Corks may be placed in the ends of the tube to prevent undue splashing of the hot metal, but one of them should have a V-shaped slot cut in the side to act as a vent for the gases.
Contributed by THOS. W. BENSON.
Electric Figure Toy
(No. 1,722,304, issued to Eisen. C. Owens.)

This invention refers to an improvement in that class of inventions known as games and toys, and particularly to moving figure toys and advertising display features. The inventor makes use of two or more doll figures, arranged so that the electric motor drive within the cabinet will actuate the figures and cause them to take on life-like movements, the limbs being suitably jointed for the purpose. Some of the features incorporated in this patent are a means for supporting and guiding the reciprocating rods in the dolls and other figures, and cushioning means for preventing noise while the device is in operation.

Electro-Agricultural Scheme
(No. 1,268,994, issued to Reginald A. Smith.)

Prof. Passenbenk provides an elevated wire rack above the plaited as shown, and these are charged with a high potential current thru a rectifier and step-up transformer. An A.C. dynamo excites the transformer, the field of the alternator being connected to a rheostat the resistance of which is rotated by a motor. Thus the resistance of the dynamo field circuit is periodically increased and diminished during each revolution, and it is designed so as to give a strongly peaked wave form. He has found that a low frequency for such a current is preferable, even as low as one in five seconds, or even lower.

Electric Fog Horn
(No. 1,270,355, issued to Jesse A. Wright.)

An electric signaling horn useful for fog signaling and other requirements, and providing a means whereby the horn may be mounted upon the pilot house so that it can be rotated within the latter and locked in any of its adjusted positions. An electric fan such as used on autos but of larger size is mounted in the smaller end of the fog horn, and means are provided for maintaining the electrical connections to the siren motor as the fog horn is elevated or rotated thru different positions.

Electrical Percussion
(No. 1,266,945, issued to John Hickey.)

Physicians and surgeons make extensive use of the art of percussion in determining whether the body is sound and healthy, and also for diagnosing bone locations and dislocations, etc. Percussion is generally performed by striking the fingers on the portion of the body under examination, but a much more satisfactory means of establishing percussory sound waves is by means of the electrical percussion apparatus here illustrated. The vibrations created by the vibrating breaker are transmitted thru a rod and cup to the body.

Sound Reproducing Device
(No. 1,266,937, issued to Herman G. Pape.)

This invention provides a new form of ear cap for telephone receivers having a number of grooves or kears molded in the side facing against the ear, so as to allow free air circulation, so that when the cap is held snugly against the ear, it maintains communication between the outside air and the otherwise closed sound chamber within the cap. These kears prevent or dissipate pressure waves, due to the vibration of the diaphragm, where waves otherwise would be focused on the ear drum and cause the sound to be muffled or indistinct, besides causing great strain on the ear drum. An adjustment screw with spring connection permits of modulating the vibration of the diaphragm. The cap also carries molded extensions around its periphery to prevent the receiver rolling off flat surfaces.

Ventilating Apparatus
(No. 1,270,355, issued to James A. Williams.)

This patent covers a unique ventilating, cooling and humifying apparatus intended for use in theaters, restaurants and the household, and which will effectively circulate, cool and humidify the atmosphere at a small expense. The object of the invention here presented is to provide means for cooling the air which will so distribute the same thru the room, so as to avoid the injurious effects of direct blasts of draughts of air usually caused by the ordinary electric fan. The inventor provides means for holding ice in a air tunnel, thru which an electric fan blows a draft of air, and the ice water is caught in a drip pan at the base of the apparatus, which is provided with an overflow outlet.

Combined Telegraph and Telephone Receiver
(No. 1,270,861, issued to Herman G. Pape.)

This is a clever combination of telephone and telephone receiver which may be used with an acoustic amplifier described by the inventor, and which should prove of considerable efficacy in telegraph offices where the sounders now in use make a bedlam of noises. For telegraphy the person using the new telephone is the only one that receives the dots and dash signals. The electro-magnet actuating the device for telegraphy operates an armature attached to a sound anvil, which latter strikes the diaphragm, resulting in a tap or click resembling that given by the standard Morse sounder. An adjustable buffer is set against the diaphragm and is to prevent continued vibration of the diaphragm and which permits only an instantaneous sound or vibration to be heard.

Dry Storage Battery
(No. 1,268,162, issued to Walter A. Crowell.)

An improved form of dry storage battery in which the electrolyte employed is non-drying, and comprises suitable absorbent inert solid matter holding the electrolyte in the cells, and the latter is distributed thru the solid mass. A specially devidied gas vent and baffle is provided so that any gas produced by the battery can escape. A series of porous tubes are placed in the battery together with the plates, these tubes serving to hold any surplus of the liquid electrolyte which may seep thru their porous walls.

Electrical Phonograph Sound Recorder
(No. 1,271,684, issued to Victor Hugo Emerson.)

A scheme for producing phonograph sound records of the disc type and providing improved means for accomplishing this purpose by utilizing an electric heating coil applied to the needle of the master record machine on which the records are made. A source of electricity and a rheostat may be used so as to control the heat applied to the needle very accurately. In applying this arrangement, the inventor uses a high degree of heat applied to the so-called "cutting stylius" while the stylus is in contact with the revolving record, making a continuous record on the record blank, and causes the stylus to be heated effectively in the air, which is a better method than the so-called induction heating.

Dental Soldering Iron
(No. 1,266,877, issued to Harry A. Orme.)

Wire solder is used in the form of a rod, which can be snapped into place quickly, and this solder feeds thru the hollow handle and carried thru the tip of the iron itself. A wrapping of asbestos is placed around the iron just ahead of the tip to prevent too much heat reaching the solder at this point and melting it. An ingenious feed lever, which can be worked by the thumb, is mounted on the front of the handle, this lever being spring actuated. The bottom of the lever bears against the solder and is toothed so as to grip it forward a given amount with each movement of the lever.
“Amateur Electrical Laboratory” Contest

In this issue we publish some interesting facts with excellent photos, describing one Amateur Electrician’s experimental laboratory. Now “Bugs” want to publish a snappy one like it each month. Here’s our proposition: Why not write up your “Electrical Lab., in not more than 500 words. Dress it up with several good, clear photographs. If we think it good enough we will publish the article in display style and pay you well for it. The prize awarded to such articles will range from $3.00 to $10.00. And “Bugs” don’t forget to make your article interesting. Typewritten articles preferred. Address the Editor of this Department.

THIS MONTH’S $3.00 PRIZE WINNER—LAWRENCE C. ARMANTROUT, MATTOON, ILLINOIS

The accompanying photos are views of my laboratory and (now extinct) Radio Station. My laboratory is combination, chemical and electrical, and the photos show most of the apparatus. I have about twenty-five pieces of electrical apparatus, such as Tesla and Oudin coils, 110-volt motors, spark coils, Leyden jars, generators, electrolyticinterrupter, step-down transformer, rheostats, tin foil condensers to 5 M.F. capacity, experimental arc, condensers for the spark coils, and 1 K.W. transformer, also condenser and rotary gap, which excite the 1 K.W. Tesla coil. The Chemical Laboratory consists of test tubes, thistle tubes, retort, delivery tubes, desiccator, hydrometer, Florence and Erlenmeyer flasks, crucible, chemist’s scale, and sufficient other apparatus and chemicals for carrying on extensive experiments. I have carried on interesting experiments with home-made Tesla tubes, the construction of which was explained in the experimenter sometime ago. I also have a couple of storage batteries and a short line telephone; and a drawing-board and drafting outfit for making structural designs, hook-ups and other drawings.

One of the photos shows my former radio station, with which I obtained excellent results, Albany, N. Y., being my record sending distance (about 900 miles). I think that the equipment needs no other description than that it is a 1 K.W. sending outfit and there are two regenerative, vacuum bulb detection receivers for receiving, as well as auxiliary Crystal and crystal detectors.

Last but not least, is the workshop in one end of my laboratory, “all dolled up” for a picture, in which I have a good stock of binding posts, contacts, machine screws, wood screws, bolts, nuts, magnet wire, spindles, strip brass and copper and other “junk” that is usually found about a “mucker’s” laboratory. The tools are coping saws, key saws, twist drills, hand drill, pliers and punches of different sizes, etc.
Phoney Patents

Under this heading are published electrical or mechanical ideas which our clever inventors, for reasons best known to themselves, have as yet not patented. We furthermore call attention to our celebrated Phoney Patent Office for the relief of all suffering daffy inventors in this country as well as for the entire universe.

We are revolutionizing the Patent business and OFFER YOU THREE DOLLARS ($3.00) FOR THE BEST PATENT. If you take your Phoney Patent to Washington, they charge you $20.00 for the initial fee and then you haven’t a smell of a Patent yet. After they have allowed the Patent, you must pay another $20.00 as a final fee. That’s $40.00! We PAY YOU $3.00 and grant you a Phoney Patent in the bargain, so you save $37.00! When sending in your Phoney Patent application, be sure that it is as daffy as a lovesick bat. The daffier, the better. Simple sketches and short descriptions will help our staff of Phoney Patent Examiners to issue a Phoney Patent on your invention in a jiffy.

Prize Winner. Solarmobile. Joy rides now being forbidden on Sundays in gasoline buzz wagons, and Doc Garfield not having clamped the lid as yet on the sun, your petitioner prays for letters Patent on a sun-fliverette. This afore-mentioned solarmobile by means of its reflector (which also shades the driver) collects free of charge the sun’s rays, which striking the thermo-cells generate juice, thence trickling into storage battery, drive fliverette motors. Compressor operates ice plant to cool driver when he gets his tire bill. The fan blows away his perspiration when he tries escaping the speed-cop. Inventor Kenneth Strickfaden, Paoli, Pa.

Trolley Regenarrative System. With blushing modesty I announce my revolutionizing inverted scenic-trolleyroad. Once trolley pole goes joyriding along the ups-and-downs track which is but a camou-full-flaged trolley wire. Due to its sinuous road it affects a 2-and-fro motion of the trolley pole. This is utilized to rotate wheel W which in turn turns one good turn into another, thus turning the pulley of dynamo which in turn intern the resultant juice into storage batteries A, B, C, D for the duration of the war. The juice runs the trolley car, surplus current going into line to run other cars. Inventor Leslie E. Neville, Leonia, N. J.
The “Oracle” is for the sole benefit of all electrical experimenters. Questions will be answered here for the benefit of all, but only matter of sufficient interest will be published. Rules under which questions will be answered:

1. Only three questions can be submitted to be answered.
2. Only one side of sheet to be written on: matter must be typewritten or else written in ink, not penciled or otherwise.
3. Sketches, diagrams, etc., must be on separate sheets. Questions addressed to this department cannot be answered by mail free of charge.
4. If a quick answer is desired by mail, a nominal charge of 25 cents is made for each question. If the questions entail considerable research work or intricate calculations a special rate will be charged. Correspondents will be informed as to the fee before such questions are answered.

BOOKS ON THE “ELECTRON.”
(953) Oscar W. Ehram, Portsmouth, Ohio, inquires:
Q. 1. For a good book treating on the “electron.”
A. 1. With further reference to the editorial in the March number of the Electrical Experimenter, entitled “Dormant Forces,” you will undoubtedly find very interesting reading, in the new work by Professor Millikan entitled “The Electron. Its Isolation and Measurement.” Our Book Department can supply it at $1.60 prepaid. Also you will find some very interesting reading along this line in the April, 1918, issue of the Electrical Experimenter.

DIFFERENTIAL BATTERY CURRENTS.
(954) A. Hering, Brooklyn, N. Y., wishes to know:
Q. 1. How to detect differential battery currents in circuits where cells are connected in opposition.

**ODD PHOTOS WANTED AT $1.00 EACH!!!**

Now is the time to make your Kodak pay for itself in a real practical way. There are after interesting photographs of out-of-the-ordinary electrical, radio and scientific subjects and are willing to pay $1.00 cash for every one we can use. Please bear in mind that for half-tone reproduction in a magazine, a photograph should be particularly sharp and clear. Of course, if a subject happens to interest us particularly well, we can have the photo retouched. For the general run of subjects, however, it does not pay to go to such expense. Therefore, please take pains to properly focus and expose your pictures. If it often happens that a really mediocre subject poorly photographed. And don’t send us plate or print “negatives”; send unmounted or mounted “prints,” preferably a light and dark one.

As to what to photograph: Well, that’s hard for us to say. We leave that up to you, and every reader now has the opportunity to become a reporter of the latest things in the realm of Electricity, Radio and Science. But, please remember—it’s the “odd, novel or practical subjects” that we are interested in. Every photo submitted should be accompanied by a brief description of 100 to 150 words. Give the facts—don’t worry about the style. We’ll attend to that. Enclose stamps if photos are to be returned and place a piece of cellophane on the envelope with them to prevent mutilation. Look around your town and see what you can find that’s interesting.

Address photos to—Editor “Odd Photos,” Electrical Experimenter, 233 Fulton Street, New York City.

CAN SELENIUM CELLS OF DEFINITE RESISTANCE BE MADE?
(956) Ray N. Coffman, Newark, Ohio, asks among other questions concerning selenium cells, if it is possible to build them with a definite, known resistance.
A. 1. Relative to the least intensity of light which will cause the resistance of a selenium cell of the Fritts or Hammer type to be lowered to its smallest value, we would say that when either of these types of cells are subjected to light rays, their resistance is decreased considerably. In making a selenium cell it is very hard to ascertain what this ratio of resistance will be. An idea of the degrees of the resistance of some of these cells can be gotten from the fact that several cells have been constructed having a ratio of 200 to 1. The amount of current that will pass when a pressure of 12 volts is subjected to the cell can be computed from Ohm’s Law in the usual manner.

Suppose the resistance of a cell in the dark is 10,000 ohms and 500 in the light, then by Ohm’s Law the current in the dark is equal to

$$E = \frac{I}{R}$$

$$E = \frac{12}{10,000} = .0012 \text{ Ampere}.$$  

The amount of current flowing in a circuit when the light is on is equal to

$$E = \frac{I}{R}$$

$$E = \frac{12}{500} = .024 \text{ Ampere}.$$  

The resistance of the relay, if used, must, of course, be added to the cell resistance, in making this calculation. Yet an electrical current can be successfully broken 4,050 times per second, in fact Dr. Nikola Tesla has invented a machine for successfully making 50,000 breaks per second. A description of this machine has been given in the February, 1917, issue of the Electrical Experimenter.

ST. ELMO’S FIRE.
(957) Gordon Jones, Jr., Cordele, Ga., inquires of the Oracle:
Q. 1. What is St. Elmo’s Fire?
A. 1. “St. Elmo’s Fire” is the phenomenon which takes place when the atmosphere is abundantly charged with electricity. It usually appears as a brilliant light on the top of ships’ masts, the points of metallic objects and other conductors from which a silent discharge usually passes. The phenomenon is most common during thunder storms and in some instances, the appearance resembles jets of flame extending several feet in length.

We would refer your particularly to an interesting article on atmospheric electricity in the July and August, 1917, issues of this Journal.

WHAT IS “LAUGHING GAS”?
(958) Patrick MacCourt, Medicine Hat, (Continued on page 408)
Free Test Lesson in Draftsmanship

Send for this free lesson which explains the Chicago "Tech" method of teaching Draftsmanship by mail. Positions at big salaries are now waiting for competent men. The call of men to the war has left vacancies everywhere. Even draftsmen of limited training and experience are snapped up and paid good salaries. You have the opportunity, learn Draftsmanship. Chicago "Tech" will train you in the most practical way in the shortest time. Mail the coupon today and let us tell you about the Chicago "Tech" method. This free lesson will show you how well equipped you are to follow Draftsmanship. Enroll in the course only if you decide that you can take it up to advantage. No cost, no obligation on you to make this investigation.

Come to the College or Learn At Home

Hold your present position while training. Our experts will instruct you by mail. Only your spare time is required. You are directly under practical draftsmen and engineers. You are taught exactly the work required in the drafting rooms of big concerns. No time to put in on unnecessary studies. This means thorough instruction and early graduation.

$25.00 to $100.00 a Week

Draftsmen earn good salaries in normal times. They command extra high salaries now—and the tremendous work to be done after the war will bring a permanent and intensive demand for good men. Make your spare time count now for a higher salary and a better position.

Easy Payments

The fees for Chicago "Tech" Courses are very moderate—and you can pay on easy terms. And also—you obtain in a few months what it would take several years to acquire by ordinary methods. You can get an early start. You are soon ready to take a paying position and to quickly get back the cost of your course.

Send the Coupon

The sooner you are prepared the sooner you will be holding a job that pays a large salary and opens the way to advancement. Many executive, general managers and superintendents began as draftsmen.

Other Mail Courses

Chicago "Tech" not only trains you to succeed in Draftsmanship, but in other important practical professions.

General Builders' Course

Plan Reading, Redrawing, Construction. Section and detail, masonry, carpentry and other problems, taken straight from the building industry.

Plan Reading for Builders

How to read Blue Print plans for every kind of building construction, how to lay out work; how to know just what the architect means. A practical course for the engineer, foreman, or draftsman. Here comes form men, foremen to become superintendents and superintendents to become contractors.

Plan Reading for Shop Men

How to read Blue Print drawings of machinery, form work, sheet metal work;4, 3½, 5½, 8½, 11½, all sizes. A practical course for the draftsman or shop man in any branch of the iron and steel trade. This course rapidly increases his earning power with this information.

FREE Instruments

FREE Lessons

This Test Lesson is given to every student free of charge. Do not lose this opportunity to learn of the higher jobs which are opening in every industry.

Chicago Technical College
1045 Chicago "Tech" Building, Chicago

Without obligation to me, please send me your FREE Test Lesson and other interesting literature covering the subject indicated below.

CORE WIRE

We have been fortunate in securing thru auction several lots of guaranteed pure, double annealed Norway Iron Core Wire and are selling this wire to "Experimenter" readers at Pre-War Prices 20cts LB.

This wire is just the thing for spark coils, transformers, etc., and it is, of course, a very much more superior product than the usual iron wire. We absolutely guarantee the quality.

If you ever thought of building a spark coil, transformer, or similar apparatus, now is the chance to get the right material for B. As far as we know this is the only lot of Iron Norway Core Wire in the hands of any dealer at the present time, and none can be gotten until after the war.

We only have these three sizes:
24 INCHES
28 INCHES
36 INCHES

Thickness about No. 21 B and 8

If either of these sizes should be too long we advise cutting the wire down yourself by means of shears. It will pay you to do so as real Norway Iron Wire, sold by a few dealers last year, brought from 40c to 50c a pound. American core wire now sells for from 30c upwards per pound.

As long as the supply lasts we offer this wire as described above to our customers at the very low price of 20c a pound. Order at once.

ELECTRO IMPORTING CO., 231 Fulton St., New York City

FOR YOU RIGHT FROM THE BEGINNING

Your Vacation Begins the Moment You Step Aboard

The Ideal Tourist Route

Picture to yourself the luxury of a magnificent, mammoth floating hotel, perfect in its comforts and conveniences, with staterooms de luxe, private baths and private balconies, applauding meals, beautiful ballrooms, entrancing music. Enjoy the grandeur of the scenery on the historic Hudson revealed by the giant searchlight.

THE ORACLE.

(Continued from page 406)

Q. 1. What is "laughing gas"?

A. 1. Nitrous Oxide is commonly called "laughing gas." It is a colorless gas with a slightly sweet taste and produces unconsciousness. It is produced in the following manner: Ammonium nitrate is heated and as the nitrate melts it soon begins to decompose with effervescence. Great care must be taken in regulating the heat, otherwise an explosion may occur.

Q. 2. What is the meaning of Analgesia?

A. 2. Relative to the statement appearing in a certain weekly paper, we believe that said statement is in error because the word analgesia is defined as "the insensibility to pain in any part of the body." However, as to the method of removing hair so that no pain at all is felt, we would say that such methods are dealt with under the subject of cataphoresis. This subject of cataphoresis has been described in "The Experimenter" by W. J. Morton, which can be procured from our Book Department for $2.50. We do not know of any case where X-rays have been used for removing superficial hair.

MOVIE TRICKS EXPOSED.

(Continued from page 371)

as clear and simple as the result is mystifying and complex. The action is obtained by the process illustrated in Fig. 7. In scenes Nos. 4, 2, 3 and 4, the usual process of motion picture photography is followed. When the director determines that it is time for His Satanic Majesty to dissolve into space, he calls "Stop" at the call between scenes 4 and 5, marked X. The camera man stops the camera, Monsieur Satan leaves the scene; Jack, the stage hand, gets a small blow for his pains, and in scene 5, on the place where Satan stood and lights the fuse. The camera immediately is started again and the ensuing explosion is filmed. After this film has been developed the printer, who makes the thousands of duplicates or positive films from the negative or negative film for general distribution to show houses throughout the States, cuts out scene No. 5, and places scenes Nos. 6, 7 and 8 over scenes 2, 3 and 4 and prints them in position. The result attained is to have Satan gesticulate and instantly a smoke screen starts from his hat and envelops him entirely. When this smoke has cleared away, lo! and behold, you find that the Kaiser's Ally has also "cleared out!"

Figure 8 shows how it was possible by using the Bray system of animated drawings, to show the action of a commercial adding machine. This operation would normally be impossible to visualize with the naked eye. Therefore it can be readily seen that with the new process it is possible to photograph and understand thoroughly the operation of the heretofore unphotographable.

The production of an animated cartoon is made by a very tedious method, extending over a considerable period of time. The artist makes a pencil sketch of the cartoon that he wishes to have photographed and this is placed under a very thin sheet of celluloid having a thickness of about 1/5000 of an inch; and possessing a marked degree of transparency. The second operation is to trace this pencil sketch onto the celluloid sheet permanently with drawing ink. One drawing is made showing the background, which in Fig. 6 is a room, showing chairs, pictures and two doors. Upon this background sheet is

(Continued on page 411)
THE wonders of electricity and chemistry —
the things that have made the reputation of
Edison, Bell, Marconi and other great men —
can be learned by the boy who has a Gilbert tele-
phone, telegraph or wireless set, or an electrical or
chemical outfit.

New discoveries and inventions, as great as those
of the past, are going to be made by boys who
commence to study these things now. They are
going to be the Edisons of tomorrow. These Gil-
bert sets are practical working outfits with which
you can learn a great deal, and at the same time
have great fun.

Perform Experiments
Learn The Secrets of Electricity

GILBERT CHEMISTRY OUTFITS — A real won-
der set with chemistry manual and laboratory
apparatus. With it you can make disappearing
ink, fire without matches, pour milk from a bottle
full of water, make soap and many other things.
Prices $2.00 to $5.00. In Canada $3.00 to $7.50.

GILBERT ELECTRICAL SETS — Complete with
manual. With it you can make your own electric
motor do electroplating, install electric bells, wire
for telephones, etc. Sets from $1 to $10. In
Canada $1.50 to $15.00.

GILBERT TELE-SET — A complete working tele-
graph outfit and manual of instructions. Price
$2.00. In Canada $3.00.

GILBERT PHONO-SET — A practical electrically
operated telephone set that can be used from
house to house or over long distances. Price
$5.00. In Canada $7.50.

The Gilbert Sets are thoroughly made and are for
sale by all dealers. Write for the Gilbert Catalog,
which illustrates and describes fully these and
many other Gilbert Toys.

Revolution

The name of Marat will forever be associated with the Reign of Terror during the French Revolution. He fell at last by the hand of Charlotte Corday to avenge the loss of her lover. This period contains more of dramatic interest than any other in the world's history. It is out of this period that the Empire was born, dominated and ruled by Napoleon. Again throughout the world thrones tremble and empires totter in the great war now in progress. Shall the new Russian Republican survive? Will red-handed terrorists again force the people to institute a monarchy to insure stable government is only one of the many great questions of the hour. How else are we to judge of the momentous questions confronting the whole world except from the lessons of the past?

The Rise and Fall of Nations

Ridpath, the historian, takes the reader back to the very beginning of civilization and traces man's career down through the long highway of time, through the rise and fall of empires and nations. Other men have written histories of one nation or period; Gibbon of Rome, Macaulay of England, Guizot of France, but it remained for Dr. Ridpath to write a History of the entire World from the earliest civilization down to the present day. It is endorsed by Presidents of the United States, practically all university and college presidents, and by a quarter of a million Americans who own and love it. If you would know the history of mankind, every sacrifice for principle, every struggle for liberty; every conflict and every achievement, then embrace this opportunity to place in your home the world-famed publication—

Ridpath’s History of the World

On account of the tremendous increase in the cost of paper and leather, occasioned by the European War, it becomes necessary to advance the price in order to cover the increased cost of manufacture. This is your last opportunity to buy Ridpath's History of the World at our present low price and easy terms of payment. We employ no agents as our low price does not permit the payment of an agent’s commission. The beautiful sample pages will give you some idea of the splendid illustrations and wonderfully beautiful style in which the history is written. Mail the free coupon below.

At a Great Sacrifice in Price and on Easy Terms

We will name our price only in direct letters to those sending the coupon below. Tear off the coupon, write name and address plainly and mail now before you forget it. Dr. Ridpath’s widow derives her income from his history, and to print our price broadcast for the sake of quickly selling these few sets would cause great injury to future sales. Send coupon today.

Supt. Long
St. Louis schools, said: "I unhesitatingly commend Dr. Ridpath’s History of the World as the ablest work on that subject which I have ever examined."

Prest. Sheldon
President New York State Normal School, said: "Ridpath’s History is a work that would be very valuable on every teacher’s table in every school library and in every home."

THE REASON

for Dr. Ridpath's enviable position as an historian is his wonderfully beautiful style, a style no other historian in any generation has ever equaled. He pictures the great historical events as though they were happening before your eyes; he carries you with him to see the battles of old; to meet kings and queens and warriors; to sail in the Roman senate; to march against Saladin and his dark-skinned followers to aid the southern seas of Drake, to circumnavigate the globe with Magellan. He combines absorbing interest with supreme reliability and makes the heroes of history real, living men and women, and all the rich and red-handed phantoms of empire in such a fascinating style that history becomes as absorbingly interesting as the greatest of novels.

Six Thousand Years of History

Here you read of the rise and fall of nations, the splendor that was Greece and the glory that was Rome. You discern the causes which have led to the overthrow of monarchies and kingdoms, peoples and races, and see how it is that the rich and defenseless nation must sooner or later fall beneath the heel of the more warlike and aggressive power. If you would know the fate of the rich and defenseless nation then read the story of ancient Assyria or Chaldea or Persia or Babylon, whose glory now is but a memory. They have been so obliterated that even the location of their splendid cities is unknown. Any person who reads History, who has red blood, who loves home and country must favor adequate self defense against the aggression of warlike powers. Dr. Ridpath gives the complete history of every race, every nation, every time and holds you spellbound by his wonderful eloquence.
ELECTRICAL EXPERIMENTER

October, 1918

MOVIE TRICKS EXPOSED
(Continued from page 408)
placed the drawing of the subject on a separate piece of celluloid; then it is photographed. Each succeeding action of the figure is accomplished by making a separate celluloid showing the figure that is to move placed in a new position. In this way, progressive action is eventually accomplished. Each new move is photographed by the camera man. In the case where a figure remains passive but where a part of the figure moves, such as an arm, the figure is drawn on a celluloid sheet and is made armless. Each successive move that it is desired to have the arm make, is then drawn on another piece and placed upon the armless figure in its proper position.

EXPERIMENTAL CHEMISTRY.
(Continued from page 396)

Upon introducing a blast of air into the heated mixture the oxygen present gives Calcium Manganit (CaMnO₄)
Ca(OH)₂ + Mn(OH)₂ + O = Ca MnO₄ + 2H₂O
This manganit is acted upon by hydrochloric acid.
CaMnO₄ + 6HCl = CaCl₂ + MnCl₂ + 3H₂O + 2Cl⁻
By this process, the manganite is the respond ingredient, can be used again and again. The oxygen of the air together with steam, is forced into the mixture of hydrochloric acid and water.

(4) By heating a mixture of 5 parts of manganese dioxide, 4 parts of sodium chlorate, and a mixture of 12 parts of subluric acid with 6 parts water;
MnO₂ + 2NaCl + 2H₂SO₄ = MnSO₄ + Na₂SO₄ + 2H₂O + Cl₂
Manganese Sulfate

(5) By heating a mixture of potassium bichromate and concentrated hydrochloric acid,
K₂Cr₂O₇ + 14HCl = 3CrCl₃ + 2KCl + 7H₂O + Cl₂
Potassium Bichromate Chloride

(6) By adding hydrochloric acid to bleaching powder or hypochlorites,
Ca(OCl)₂ + 2HCl = 2CaCl₂ + H₂O + Cl₂
Bleaching Powder Chloride

(7) The Deacon Process is based upon the oxidation of hydrochloric acid gas by the oxygen of the air, over pieces of brick which have been saturated with copper chloride and heated to about 440 degrees Centigrade. In outline, the reaction is:
2HCl + O = H₂O + Cl₂
This is supposed that the copper chloride acts as a catalytic agent in the liberation of a portion of its chlorine, and withdrawal of it from the hydrochloric acid, thus the influence of the oxygen of the air.

Properties: Physical:
1. Chlorin is a yellowish-green gas, of a suffocating and stifling odor, and when inhaled, exerts a corrosive action on the mucous membranes of the air passages. It is irritating and intensely poisonous, death resulting from inhaling it in quantity. The "Huns" are reported as using this fiendish gas to check the advancing drives of the "Allies" in the present World War, and it is a foregone conclusion that no other civilized nation would stoop to such a vile means of not only killing, but severely impairing the respiratory organs of their opponents.

ELECTRICITY as experts know it

Learning electricity as you would in the actual PRACTICE — in accordance with the methods employed by the highest paid electrical experts in America. The New McGraw-Hill Library of Practical Electricity contains the actual working facts which you need in order to succeed in the electrical field. Terrell Croft, formerly with the Westinghouse Company, makes the conquest easy for you. Read the course at home or slip a volume in your pocket for use on the job.

Not a correspondence course
This is NOT A CORRESPONDENCE COURSE — but a home-study course, complete in itself and thoroughly up to date. The set of 8 flexibly bound, pocket-size volumes contains complete practical education which would cost several hundred dollars procured from any other source. You pay only $16, for you may understand it, study, and take nearly all the tests. You may pay $2 per month, or $30 in 10 monthly installments. R. M. HUNTINGTON, the present head of the Westinghouse Electric and Manufacturing Company, has selected, arranged, and supervised these volumes.

Recently completed, The New McGraw-Hill Library of Practical Electricity
by Terrell Croft, formerly with Westinghouse

Easy Payments, $2 per month—Complete course 8 vols. only $16
After examining the books under our 10-day free examination offer you will readily understand why students and electrical workers are so enthusiastic about the "Craft Library." No amount of description can possibly outline to you the importance of these books in the electrical field today. You must see this flexibly bound Library and run through its 9,500 pages and clearly drawn illustrations to realize the value of the books. They are practical treatises and are written by men who understand what it means to the student and the electrical worker. The volumes cover Practical Mathematics, Practical Electricity, 2 Vols.; Electrical Machinery, 2 Vols.; Central Stations, 2 Vols.; Wiring for Light and Power, 2 Vols.; and Practical Electric Illumination, 2 Vols.

Examine this new Library and find out for yourself why they improve working methods and form a sure, short-cut to bigger pay.

Be guided by a Practical Man

Be guided in your study of electricity by an experienced Electrical Engineer of high professional standing. Terrell Croft, author of 7 of these volumes, climbed from the ranks to the top of his profession with the Westinghouse Company. He gained his knowledge with his elbows rolled up, and has met your problems in advance. He tells in plain, understandable language how to proceed by the best and most practical methods.

Easy Payments Pay for the course as you go along at $2 per month. One of the volumes will give you your prepaid subscription to ELECTRICAL EXPERIMENTER.

Just Send the Coupon The coupon below is for your conveniences in examining these practical books. It obligates you in no way; it may easily be torn, returned, examined, and enjoyed at your own leisure. If, after examining them, you are convinced of their power to help you to the heights you desire, send $2 to our office and the balance at the rate of $2 per month until $16 has been paid.

Some Music Masters

—and not the least of these is the Ellis Music Master, for it makes possible the perfect reproduction of all the wonderful vocal and instrumental compositions of all the music masters. It brings to you the "living voice" of all artists whose beautiful melodies have been recorded on discs.

ELLIS "MUSIC MASTER" REPRODUCER

makes your phonograph or talking machine truly delightful. It is the "missing link" that overcomes all faults of ordinary reproductions. It does away with that harsh, metallic, ringing sound that is common to all machines using ordinary records. It makes that disagreeable, nasal, "phonograph voice" a thing of the past. It reproduces faithfully and in true tone values, every note that is on the record. It gives you the sensation of hearing most delicate trills of accompaniments that are lost with ordinary reproducers. The Ellis "Music Master" is made for all machines using disc records and will give you renewed delight in hearing your favorite music. It makes possible absolutely perfect reproduction of the music. The cost is little, but the pleasure is great.

Write today for circular.

J. H. ELLIS, P. O. Box 882, Milwaukee, Wis.

What $15.00 Will Bring You from the Nation's Capital

Washington, the home of the Pathfinder, is the mecca of civilization; history is being made at this world capital. The Pathfinder's illustrated weekly review gives you a clear, impartial and correct diagnosis of public affairs during these strenuous, epoch-making days.

The little master of 50 in stamps or coins will bring you the Pathfinder 13 weeks on trial. The Pathfinder is an illustrated weekly, published as the Nation's center for the Nation; a weekly that prints all the news of the world and tells the truth and only the truth in its 4,000 columns. This review fills the bill as an educational, entertaining and delighting magazine. It keeps you posted on what is going on in the world, all the best world news, the latest financial developments, the last in the political, and all the world's progress.

Pathfinder, Box 76, Washington, D. C.

Wireless Taught by Mail

DRAFT MEN—THIS IS YOUR OPPORTUNITY

90,000 Wireless Operators, Men and Women, urgently needed for Army, Navy and Aviation Service Excellent opportunity to win promotion in commissioned and non-commissioned grades with Maximum Pay. Wireless work trains you for position as Commercial Operator, or after the war, with pay up to $300 a month.

Complete Course by Mail in Ten Weeks

Start sending NOW in spare time at home. Complete practice apparatus sent with first lesson. We help you choose any branch of Radio Service you select. Write TODAY, for full particulars. A Postcard will do.

TELEGRAPH PICTURES

This unique set of wiregraph telegraph machines, Picture Telegraphing Machines will telegraph pictures, maps, drawings, and hand-writing. The inventors of the Leishman systems recently telegraphed a picture of President Wilson as far as from Paris to Chicago.

Only $15.00 for a complete set of two machines

L. J. Leishman Co., Ogden, Utah

Drying Tube Which May Be Inserted Between Generator and Receiving Bottle, as Described in Experiment No. 145.

EXPERIMENT NO. 145

Preparation from Hydrochloric Acid and Manganese Dioxid.

CAUTION!!! Chlorine is a poisonous gas, and great care should be exercised in handling it. Avoid inhaling it. Inhaling ammonia or alcohol will counteract some of its effects.

Put 10 grams of manganese dioxide (the granular is preferable to the powder in this experiment) into a Florence or Winslow flask and make the connections as shown in Fig. 133. Run the thistle tube thru a two-hole rubber stopper thru a short right-angle connector to the receiving bottle as shown. A drying tube of the form shown in Fig. 134 may be inserted between the angle connector and the flask to the delivery in the receiving bottle. If this dryer is used it should be filled with calcium chloride, which was added by tying the end of it with a rubber tube. Set the flask on the ring stand or tripod over gauze or asbestos, and apply only a moderate heat, first pouring in thru the thistle 25 or 30 cc. of hydrochloric acid and rotating the flask so as to mix the solid and liquid. As the experiment progresses it may be necessary to add more of the reagents, especially the acid (the gas escaping becomes white), shaking the contents of the flask in each case. Watch the action in the generator and flask and have other bottles to replace the first as soon as it is full, or a little before, which can be told by the color. Collect three or four
bottles, covering each with a glass plate. Test the action of the gas towards combustion, by thrusting a lighted splint into the flask.

EXPERIMENT NO. 146.
Prepare a hydrogen generator and cause the hydrogen to be liberated by permitting hydrochloric acid to act upon zinc. Use only a small quantity of zinc and have some water in the flask to condense the acid in steam, which may pass through the tube.

Instead of collecting it under water as we did in our experiments with hydrogen (Demonstration No. 139), bend a small glass tube as shown in Fig. 135, with a small opening at the end and reaching nearly to the bottom of a large bottle. When the hydrogen escapes quite freely, test it for air by applying a lighted splint, and when all the air is expelled, ignite the hydrogen at the capillary.

(To be continued)

WHY NOT ELECTRICITY FROM THE OCEAN?

(Continued from page 377)

To those who have not experimented with a float mounted on such a body of water as to give it appreciable power whenever waves of the proper size break on it, such as on rivers, lakes, or perhaps on the ocean shore, it is probably a little difficult to perceive that such water power could provide any appreciable amount of energy. The reader may form a good idea as to just how much power even a small wave will give by an instance which the author noted not long ago. In this case, the float (on the shore) measured about ten by twenty feet and was used as a launch landing on a river a mile wide. More than once the steamboats plying this river past a distance of half a mile, i.e., in midstream, the waves created by the passage of these boats was sufficient, when they reached the shore, to oscillate the float (on which rested one end of a fairly long and heavy gang plank) with surprising power, and to give an idea of just how powerful this action was, it can be stated that with four people, weighing about six hundred pounds in the aggregate, the float was thrown rapidly up and down on its guide poles a distance of about four feet, much as if it had been merely an arm attached to the gang plank. By comparison it is easy to see that the ocean waves, which are much more powerful on the average, would exert an infinitely greater power on the water. Thus, if constructed, the work expended by the waves amounted to 2,400 foot-pounds or considerably more in the aggregate. The float was thus capable of lifting a much greater weight than that mentioned, but this will serve as a practical example to show the great power possessed by a moving body of water.

AN ELECTRIC SPEED AND DIRECTION INDICATOR FOR TRANS-ATLANTIC PLANES.

(Continued from page 375)

Though the floating log being pulled thru the water would have to be periodically handled aboard to prevent it from rolling over as to reduce the friction of the dials. Several minutes would be consumed undoubtedly in hauling up the log and taking the indication from place to place, so some authorities have mentioned that this might cause an error as great as two per cent, owing to the time during which the log was out of the water, and the increase in weight down over the board, not then be recorded by the mechanism.

The drawing herewith shows the simple arrangement of electrical apparatus in studying the successes of any of our big money makers.

Interesting and inspiring are several cases that have come to my personal attention, because the same methods are open to us all. A good example is the story of a boy of twelve who was a great success. He started out in life with only a few dollars, yet he made good use of them. He bought a newspaper and circulated it, and by the time he was a dozen years old he had a large circulation and was making money. Another example is the story of a young man who worked in a big factory. One day he met Mr. W. M. Taylor, the noted efficiency expert, who read him the following:

"Power of Will." He did so, applied himself to the training of his will, and in less than one year his salary was increased to more than eight times what he had been earning.

Then there is the case of C. D. Wrenchen, General Agent of the Northwestern Life Insurance Company, who came to my office a week ago and told me that he had made $200,000 without speculating and today is earning $500,000. He is only thirty-five years old and he frankly credit his good fortune to Prof. Frank Chapman Haddock and his very re- markable methods in the matter of teaching. Another is the story of a young man who worked in a big factory. One day he met Mr. W. M. Taylor, the noted efficiency expert, who read him the following:

"Power of Will." He did so, applied himself to the training of his will, and in less than one year his salary was increased to more than eight times what he had been earning.

In this new book Prof. Haddock, whose name ranks with Bergson, James, and Royce in the scientific world, has for the first time a practical, simple system of rules and exercises that has completely revolutionized the lives of thousands of people.

It is a practical, simple, rule of life, and it is just the thing for anyone planning to be a master of the mind and training as any muscle of the body. "Power of Will," is being distributed free by the Pelton Publishing Co. of Meriden, Conn. Any reader who cares to examine the book may do so without sending any money. It is free, and after five days, you do not feel that this book is worth the 50 cents for it, return it and you will owe nothing. Some few doubtfuls will scold at the idea of will power being the key to wealth and achievement. But intelligent men and women will investigate for themselves by sending for the book at the publisher’s risk.

Among the 250,000 owners who have read, used, and praised "Power of Will" are such prominent men as Supreme Court Justice Parker, Wu Ting Fang, ex-U. S. Chinese Ambassador; Lieut. Gov. McNevile of Nebraska; Assistant Postmaster-General Brit; General Manager Christenson of Wells Fargo Express Co.; R. St. Louis Lewis; General Arthur Capper of Kansas and thousands of others equally prominent. As a first step in training, act on your present impulse to write a letter or address a man, or to hold a conversation. Then send a copy of "Power of Will" immediately. It will be sent on receipt of a card, postpaid.

P. S. It is recommended that you get a new impression on your money by making it a habit to write a letter or address a man, or hold a conversation whenever you are uncertain which of your two hands to use. The "Power of Will" is the key to success.

How a Failure at Sixty Won Sudden Success
From Poverty to $40,000 a Year.
A Lesson for Old and Young Alike.

By R. D. RAINES

The old-time millionaire "made his pile" by speculation, overwork and self-denial. A much bigger army of men today are piling up millions without denying themselves the comforts and little luxuries of life—by giving up poor jobs for better ones, by preserving their health and strength, and by retaining their manhood and independence all through. The secret of success is a new secret among the well working.

Our story is about one who learned it—an old man who got hold of some of these young ideas. If you could have met him in the summer of 1915 you would have pitied him. For forty years he had been true to the old creed—hard work, long hours, patience, faithfulness and economy. By dint of scrimping and scraping he would save a few dollars only to have them swept away by a season of illness in his family. And his reward? It came at sixty. When he was thrown out of employment onto the scrap-heap. His old-fashioned rules for winning success had failed to work. "What was wrong with them, said he to himself?"

He reviewed, one by one, the careers of some of his old business associates who had prospered, and suspected everyone of being him. He turned his attention to several young men who were forging rapidly to the front. Suspicion became conviction. In one respect all those men were identically alike. The climbing youngsters and the prosperous oldsters were strong-willed fellows of determined purpose.

It was almost amusing the way he be and others of his kind scurried to get out of the way of these men whenever they set out to accomplish any purpose. Slowly the full truth came to him. Success was not a matter of age. It was not luck. It was not even a matter of opportunity. It was simply a question of dominating the idea of success, of laughing at the brooks, the barriers, the obstacles. It is only a question of time. If you ever hesitate, it is because you have not set your mind on the result."

For a long time he had believed he could make a success in a certain line of manufacture. He had some new ideas about it. But he had never been bold enough to even mention his thoughts to others. Now he was sought out by some business friends. Instead of begging a small loan with which to pay his rent, he presented and explained his plans for launching a business of his own. His friends’ first response was to smile. But as they listened they were struck by a new note in the old man’s voice. He insisted that he possess it in his hearing; his tone was magnetic, compelling; his argument sound and convincing. This gentleman was not afraid to spend every penny of the loan and at the end of one year his books showed profits of $2,000, and his second year’s operations promised $35,000 to $40,000, a fortune.

A better understanding of the tremendous power of the human will as a force in business and in fortune building may be had by
NEW DEVELOPMENTS IN TELE-PHOTOGRAPHY.

(Continued from page 387)

A drum of non-conducting material, preferably on the same shaft as the sending and receiving brushes. These drums, in longitudinal alignment, are a very thin strip of copper or other conducting material and two resistance elements. All of these are electrically connected to the shaft. The current to these resistance strips is supplied from opposite sides, the purpose of which will be obvious later. Three brushes—one for the copper strip, and the other two for the resistance elements—are arranged so as to make contact with these as the drum revolves.

When sending a picture, the thin copper strip is connected thru the shaft to one outgoing wire; and the brush is connected in series with certain certain angle of the "log line" with his craft, altho the relative position of the log could be determined in this way at any time, even at night when it is dark, and the log appears as a point. A small calliope is blown, and a bull's-eye attached to the front of the log, as here shown. In practice the long line is simply attached to a lever mounted on the aeroplane so as to cause an indicator needle to move in the cockpit.

The synchronizing impulse is necessarily heavy to distinguish it from the picture transmitting current. This being the case, it is imperative to provide some means to keep the heavy synchronizing impulse from reaching the circuit that receives the picture, as it would burn out the magnets. The seams of the picture are arranged to come in line with the synchronizing strips on the non-conducting drum, so that the heavy impulse is never received when the picture itself is being transmitted, but while the seam is passing. It is, of course, necessary to have the synchronizing impulse received when the brushes at the receiving machine are passing the log, and so the log must be remembered for the sake of clearness this will be explained later and must be taken for granted for the present. It will be obvious that the current always comes when the brushes and synchronizing strips make contact, it is easy to arrange other contacts and brushes so that the current will pass thru the synchronizing circuit while this part of the cylinder is passing, and so that the current at all other times passes into the circuit that receives the picture proper. So long as the cylinders are revolving in synchronism, this means can be relied upon to distribute the two currents with perfect equality; but until synchronism is established, at the beginning of a transmission, another arrangement accomplishes the purpose.

The system operates strictly as before, except with the means for getting the resistance strips to pass beneath the brushes when the synchronizing impulse is received.

The principal part of the mechanism is another gravity relay. In its first position, this serves to connect the motor with its source of current through a circuit containing considerable resistance. This causes the motor to run slower than the one on the transmitting instrument. This being the case, the heavy current is reduced (and it takes only a few seconds—seldom more than ten revolutions) when the resistance elements are under the brushes. The motor is then permitted to pass the brush thru the coils of the relay, which throws the gravity arm, causing the resistance in the motor connections to be short-circuited, so that the motor then runs at the approximate speed of the motor of the transmitting machine.

Until the relay is operated, by the presence of a current in the synchronizing circuit, the circuit that sends the picture remains open. This is necessary to keep the coils from the light being burnt out, as the currents cannot be distributed until the brushes and resistance elements are in contact when the synchronizing impulse comes. This relationship is established, the relay, which operates only under the heavy impulse, is thus in the picture circuit to be closed. This relay performs the two-fold purpose of closing this circuit and of short-circuiting the resistance that is in series with the motor.

It has already been explained that the current is equal in the two brushes that touch the resistance strips providing the current is received when they are at center...
Thousands of skilled Electricians are needed. The demand is becoming more urgent every day. The Government is employing every one they can get which is causing a great scarcity throughout the country and big salaries are being paid everywhere. Right now is your big opportunity. Make up your mind now to prepare for one of these big jobs and then get here as quick as you can for your training.

**Earn $100.00 To $300.00 A Month**

In the Electrical business. Come here where you will be trained in these great $100,000 shops. Experts show you everything and you learn right on the actual apparatus. You work on everything from the simple bell to the mighty motors, generators, electric locomotives, dynamos, switchboards, power plants, everything to make you a master electrician. We have thousands of successful graduates. Just as soon as you have finished we assist you to a good position. We now have more positions than we can fill. Think of it.

**Drafted Men Read This**

It will only be a short time until you are called into service. This is a war of skill, brains, and machinery. Uncle Sam must win this war and must have tens of thousands of men skilled in modern trades and professions such as Electricity, Drafting, Plumbing, and Sanitation. Such men will be quickly recognized and given an opportunity to rise. It is not too late for you if you act at once.

In most cases those of our students in the draft, who have been called before completing their course, have been given an extension of time by their board sufficient to finish their course, owing to the great need of trained men in these lines in the Government Service.

**Prepare to Serve Your Country**

**Learn Drafting**

Skilled Draftsmen are always in demand. Our courses are thorough—short—practical, preparing a man fully to hold a position of responsibility. We have more positions than we can fill. We also have thorough practical courses in Plumbing and Heating and Motion Picture Operating.

**Earn Your Way**

Many students earn a large part of their living expenses by doing a little work in their spare time. Our employment dept. furnishes these positions without charge.

**Mail Coupon for Free Book NOW!**

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.
**Learn Aviation Mechanics**

Train yourself for the Aviation Service by enrolling yourself at the Preliminary Ground Opehers in Aviation Mechanics, affording preparatory prior to entering Government Ground School, covering aero-dynamics, aero-engines, rigging and Lewis guns, etc. Previous experience unnecessary.

**COMPLETE COURSE including Aero-engine course, taken in six weeks (three hours daily) $60**

**Special Aero-Engine Course (three weeks) $35**

**Wireless Course (four weeks) $25**

Write for our Illustrated Booklet "H," "A Message to You on Aviation".

---

**Violet Rays**

Wonderful HEALTH and BEAUTY GIVER

Electricity from your light socket transformed into the greatest health-giving agency known to Science—VIOLET RAY—powerfully effective, yet soothing and gentle in action. Benefits of tremendous value of electricity absorbed by the human body without any slightest shock, muscular contraction or pain of any kind; pleasant and perfectly safe.

**RenuLife/Violet Ray High Frequency Generator**

Used and endorsed by physicians and beauty specialists; saturates the body with soothing, invigorating, curative violet rays, producing New Life, Power and Beauty; purifies the blood stream and brings the circulation to parts treated, renews and builds up.

Every home should have this marvelous invention; benefits everyone per son in sickness or health: smallest infant, sick or feeble. It is not a cure all—but treats successfully a wide range of ailments because it is systematic in effect—relieves the symptoms while steadily removing the cause; bring back normal conditions.

**Treat Successfully**

**Rheumatism**

**Narthritis**

**Lumbago**

**Chest Pains**

**Catarra**

**Headache**

**Ear Diseases**

**Hardening of Arteries**

**Wrinkles**

**Skin Diseases**

**Falling Hair**

**Etc. Etc.**

Treatment Chart furnished showing use for over 100 ailments.

---

**BOOK REVIEW**

This exhaustive Cyclopedia of Applied Electricity covers a very wide field of electrical engineering as the reader will perceive by glancing at the contents of the various volumes as outlined below. The general style of the treatment is such that anyone with an understanding of the English language and with ordinary common school education can readily learn from these books the successive problems and the application of electricity to telegraphy, telephones, electric lights and power distributors, wireless telegraphy, electric welding, etc., etc.

Volume one covers the elements of electrical study and starts off with the principles of the magnet and magnetic induction. The style of treatment by the authors of these books, all of whom are well-known instructors in well-known universities and colleges, is very clear, and the illustrations are particularly well arranged so that the layman or young student can gain a true idea in every case of just how a certain experiment or test is to be properly made. With the possible photographs or diagrams to show the commercial instruments and apparatus, and some blurring of the lines between the necessary diagrams with photographs of actual commercial apparatus the student or general reader cannot fail to gain a thorough idea of each instrument described and how it operates. Volume one continues with the study of electricity, primary cells, the principles of the telegraph and telephones, the principle of the electric current, the application of Ohm's law to both series and parallel circuits, etc. Considerable space is devoted to the requirements of the Fire Underwriters in installing electrical apparatus, and the various approved types of installation of this nature are well illustrated by means of photographs and diagrams where necessary. Another section deals with electrical measurements and coverage, the principle of the galvanometers, electrometers, Kelvin balance, wattameters, kilowatt meters, power-factor meters, Wheatstone bridge for measuring resistance, the Megger, the potentiometer, etc. The following chapter takes up the method of measuring tests on D. C. as well as A. C. circuits, and also in polyphase circuits. The mercury motor watt-hour meter and ammeter are described and illustrated, also the testing of watt-hour meters and the method of testing integrating watt-hour meters. At the end of the volume there appears a number of review questions which will give the student a good idea of how the various problems are worked out.

Volume two takes up dynamo-electric machinery. The first part of this volume deals with the laws of electro-magnetism, especially as they are related to dynamos and motors, and gradually the student is educated by easy stages to the well-known laws of the magnetic circuit. The elements of armature winding are clearly explained with many excellent illustrations. The principles of commutation are made particularly clear by means of numerous special drawings. A very complete study of the design of a continuous current generator of one hundred kilowatt output is given, together with every detail and calculation for the propounding of the mechanical and electrical parts of the machine down to the last bolt. This section will appeal particularly to those interested in dynamo and motor work and includes numerous tables giving data on various designs of dynamos from one kilowatt output up to several hundred kilowatts. Another chapter deals with the various types of generators and motors, and this chapter is illustrated with numerous photographs of all the standard types of dynamos and all well-known commercial makes, so that the student will quickly recognize each respective type of motor or generator when he sees it for the first time after studying the text. The latter part deals with alternating current generators and motors and a number of questions are appended at the end of the volume for the student to work out, which cover the text matter studied in the various chapters.

Volume three takes up the study of the direct current motor in detail, also the management of dynamos and motors including their installation and maintenance as well as the testing out of motor and dynamo troubles on the job. This volume also takes up the principles of electric lighting.

(Continued on page 418)
New Way to Master Electricity

HERE at last is what you’ve been looking for. All there is to know about electricity written by twenty-seven authorities in such easy to understand language that it makes studying more like a game than like work.

Tells all about elements of electricity—electrical measurements—underwriter’s requirements—theory calculation, design and construction of generators and motors—dynamo-electric machinery—lighting machinery—power transmission—electric railways—power stations—switchboards and switching—and electric chemical—electric elevators—electric welding and heating—wire and wireless telegraphy.

In fact this remarkable cyclopedia of Applied Electricity explains everything from wiring a doorbell to the newest wireless discoveries. There is no other work like it.

FREE ADVICE With your set you receive a full year’s consulting membership. This entitles you to the advice and assistance of our electrical experts without one penny of expense. Many of our customers say this personal help has been worth hundreds of dollars to them. Yet it is yours free if you act quickly.

7 Cents a Day—Half Price

If after examination you decide to own this wonderful seven volume set, send only $2 within a week after receiving the books and then only $2 a month—an average of only 7 cents a day—until $19.80—the special half-price is paid. The regular price is $35 so quick action is necessary.

Send No Money

Not a penny. Merely fill the coupon and you will receive the complete cyclopedia of Applied Electricity for free examination. Keep it a week then if you can afford not to become a master of the electrical subjects you’re interested in, in this simple, easy, inexpensive way, send the set back and you owe nothing.

ELECTRICAL EXPERIMENTER
October, 1918

BOOK REVIEW.
(Continued from page 416)

The opening section on direct current motors is up to date, and is very clearly illustrated by numerous diagrams showing boxes and other components. Speed controllers are connected up to series, shunt and compound wound types. Numerous excellent illustrations are inserted throughout the work, showing both large and small commercial applications of the equipment, and these tend to broaden the mind of the student and to thoroughly familiarize him with the technical arrangement of belts, chains, etc., in industrial plants. One of the latest in the self-driven motor-driven machines, and shows how motors are applied to various types of machines, and some excellent tables are given of the horsepower required for driving these various sizes and types of machinery. Open-end dynamo trouble is well systematized and arranged so that the reader can turn to the remedies for any certain trouble. The section on electric lighting is very complete and open with circuits, and of the electric light head light systems, with complete wiring diagrams. The measurement of candellum is well explained and a very interesting final chapter covers isolated lighting plants such as those found in suburban homes.

Volume four covers alternating current machinery, and in this one of the most interesting principles of alternating currents are combined, as well as the arrangements of various types of alternating current machinery. The manner of expressing this principle is important: The various devices of alternating current machinery; and clearly and also completely explained. Without the aid of advanced mathematics, and therefore the student of electrical matters will find this one volume particularly readable and instructive, should be the one to be of great assistance to the student who has never heard of alternating currents. It is also the best and the most complete method of changing the direct current dynamo into a rotary dynamo, and the method of changing the operation of the various relations between the operation of the induction motor and the synchronous motor.

Volume five treats on power transmission, and it includes the theoretical and practical considerations in connection with the transmission current transmission circuits. The section on the design and calculation of transmission lines is very clear, and numerous tables containing the necessary data to be used in the formulas applying to the work are included in the text. Such practical and theoretical background consideration are taken up, and various arrangements of the transformers are described in detail, also the advantages and disadvantages of different arrangements. The section on electrical railways is written on the subject as a guide for the engineer, and is very well illustrated. Detail drawings are given of the various types of electric railway cars, and motors of the latest type are included in this treatise. Other features treated on are lighting and heating systems for electric railways, electric railway power plants and their operating characteristics, electrical transmission systems for railways, track construction, electric locomotives, etc. At the close of this volume a full-page free form description is given together with detail drawings of the latest electrically controlled two-coupled wheel and a section is also devoted to self-propelled railroad car type.

Volume six. Power stations and applied chemistry are here discussed. This book deals with electric power stations and the elementary principles of power station design are given in a simple manner. This volume can quickly progress. Various applications leading to the design of a various type. The first chapter takes up in detail the various factors governing the most desirable location of a power station, and shows the attention this is calculated so that the station will be as near as possible, the factors. The design and of the electrical load. The test then proceeds with the design of power stations, arrangement of boilers, etc., and also the installation of water tanks where water supply is required. Part of this volume is devoted to various types of electric sub-stations and switchboards, and the necessary instruments to be used on these boards for various sizes of plants. It is regrettable that the power is not larger, as hydro-electric plants are the coming thing and are being developed more and more every day. Considerable space is devoted to the study of storage batteries including their relation to the various types of power stations and the necessary instruments to be used on these boards for various sizes of plants. It is regrettable that the power is not larger, as hydro-electric plants are the coming thing and are being developed more and more every day. Considerable space is devoted to the study of storage batteries including their relation to the central station, where they are used.

You benefit by mentioning the "Electrical Experimenters" when writing to advertisers.
to carry the peak of the day's load, etc. The complete manner in which the storage battery is explained and illustrated is very good indeed. The electrode and battery are described in detail. Storage battery charging systems are covered very completely. The section on storage batteries described in detail. Volume seven, Telephony and wireless, both wire and wireless, electrical elevators, electrical heating and welding are the subjects treated in the seventh and concluding volume of the Cyclopedia. This volume treats the first chapter on modern land and submarine telegraphy, and the subject is very well handled indeed. The various types of telegraph circuits are discussed in a clear manner, and all of the different instruments used on the circuits are illustrated both by diagrammatic illustrations and half-tone cuts of the actual instruments. The various forms of telegraph signals are given, and a section is devoted to the latest developments in telegraphy, the typewriter key-board printing telegraph, such as the "Markram system." The various types of multiple printing telegraphs including the well-known Bokor system are illustrated and described as well as automatic and high speed telegraph transmitting and receiving systems. The section on cable telegraphy is well written, although it is somewhatbrief in scope. The next section deals with wireless telegraphy and the basic principles on which this branch of science rests are clearly explained. This section is the student a good idea of the general principles of wireless telegraphy, but it is more historical in its treatment than anything else. The concluding chapter of the wireless section treats on wireless telephony, and explains the principle of the telephoto, as well as the earlier systems used by Ernst Ruhmer and A. F. Collins, including the arc system of Poulsen. The section on elevators is made of extreme practical value.

THE REVOLVING MIRROR AND SPARK DISCHARGES.
(Continued from page 390) off into space. Had the oscillations continued for one second, 223,500 waves would have been produced and they would have been spaced 6,000,000 miles apart. In other words each of the 20 waves actually produced was 186,000 + 223,500 = length in miles or 0.832 mile, or 1,465 yards. A wave of this kind the helix would read 1,465 yards wave length if correctly calibrated.

NEW DEVELOPMENTS IN TELEPHOTOGRAPHY.
(Continued from page 414) and that the differential effect increases the further they are from center, one brush having the greater current above center, and the other brush the greater when below center. Each brush is connected to a solenoid, into the centers of which protrude the horn-shaped arms of a rocker that pivots on a friction bearing. A hand on this rocker forms the contact on the sliding contact rheostat in series with the coil. As long as the machines are running in synchronism, the current in the solenoids halts the arm so that the current to the motor is 60% in its normal position. This is a slight deviation in the synchronism, there is a change of current in the solenoids which pulls the arm to one side and this however moving the rheostat contact so as to increase the motor current if it is too slow, or less current if it is too fast. This system of synchronizing is positive, and because of the resistance of the rheostatic circuits, a very slight change causes the apparatus to respond.

When the picture has been received, the cylinders continue to revolve until they have advanced far enough to strike the arm of the starting relay and thus put it in its original position, breaking the motor circuit and stopping the machine.

Loose Leaf Device.

(261) L. Mac Neil, Mansfield, Mass., writes us as follows: "As you know there are many styles of loose leaf books on the market, and most of them have to have a special paper that is supplied by the same people that put out the books. Because of the rings in the book, this paper has to be punched before it leaves the factory. A man could buy a paper punch for each kind of loose leaf book he has in his office, but it would not keep its punch, and take up too much time to punch all the pages for the book.

My idea is to have an adjustable paper punch. It could be about twelve inches long, and at least six dials, that could be spaced any distance apart, according to the needs of the man. A man could have as much paper as he wanted cut to the desired size, and have his book sheets cut to the size and type he desired them to be used them. Will you kindly give me your advice in this matter?

A device of this kind is not patentable. Unless there were entirely new features connected with this device, you could not obtain a patent on the same. Just by making a punch die adjustable does not make it patentable.

Projector.

(262) C. Reginald Wilson, Louisville, Pa., has an idea which concerns a twelve-inch shell to be used in a cannon. It contains a central cylinder shape, which he proposes to fill with nitro-glycerin, while another ring-shaped partition contains poison gas. The idea is that when the shell explodes the nitro-glycerin would force the gas out. Our advice on this is asked.

A. The idea is entirely impossible. Nitro-glycerin, one of those explosives which detonate violently under concussion, consequently, before the shell would leave the cannon, it would most certainly explode from the shock and incendiary effects of the explosion. The chemical, gas-poison shells, which are now being used at the front, make use of a certain explosive which opens up the shell, forcing the gas out. Usually, a very small amount of explosive is used for this purpose. There is, of course, nothing new in an idea of this kind.

Rubber Stamp.

(263) Dan Coller, Mountain Grove, Mo., says, "Noticing some Boy Scouts with a blackens emblem and merit badge after their signature, I thought of having a stamp with movable figures like the dating hand rubber stamps used in offices, but instead of having the figures or numbers, I propose using the Scout Emblems and merit badges. Is such an idea patentable?"

A. This is decidedly not patentable; just because you are the Boy Scouts' insignia instead of figures or letters does not make an idea patentable. Otherwise, it is a good idea. There are many good ideas on which people have made a lot of money which cannot be patented. It is only unusual that the patent that counts.

H. GERNSBACK  

Testing Device.  
(264) Clarence N. George, Portsmouth, N. H., has developed a very ingenious scheme for testing our telephone wires. 

It has been found that many times it was necessary to run a number of circuits between two points where it was not practical to run a lead cable. These wires are all of the same color and it becomes necessary to test each pair before they can be connected to the proper lines and a branch exchange switchboard. The method usually practiced is to station a man at one end of the wire with a test telephone and have another man at the opposite end with a test phone and dry cells. In this way the right pairs are picked out. 

A. The idea which our correspondent advances is a very ingenious one and more or less simple. We are sorry we have not available space to show the entire device, but we are certain that our correspondent's apparatus can be patented. We advise him to get into touch with a patent attorney. 

Combination Device. 
(265) W. R. Charles, Knob Noater, Ma., shows a sketch which embodies a combination tool for pocket use, comprising a gas tank key, a small screwdriver, a bottle opener, owner's name and a hole which serves to put on the key ring. Our advice is asked. 

A. We see nothing fundamentally new in this device. It seems to us we have seen something similar before. 

Telephone Receiver. 
(266) Benson Freeman, Jr., Atlanta, Ga., submits a telephone receiver working on the principle of a suction cup, as the illustration shows. Instead of having an electric magnet in the shell of the receiver, this receiver takes the form of a tube 1 1/2" long, 1" in thickness, the inside being hollow, wound in the usual manner. The diaphragm is the ordinary one except for the fact that in the center a piece of soft iron or steel 1/16 of an inch thick and 3/4 of an inch in length fits into the hollow space in the rubber tube. We think that a patent might be secured on this receiver. 

A. This is a very old idea and has been described over twenty years ago. This is the principle of the so-called "soft cylinder" on one end. This cylinder has a cup-shaped depression as shown. As the door is pressed against this piece of rubber, it forces the air out of the cup and, therefore, makes a partial vacuum, holding the door firmly. The device can be fastened on the floor or against the wall. The door can be disengaged with a quick jerking pull. Is the idea patentable? 

A. This is indeed a very good idea and we are certain that a good patent can be secured. We should think there would be a good demand for a device of this sort, providing the article can be made to function surely in every instance. 

We have found, however, that the one trouble with suction cups of this kind is, that unless they are large they will not function well unless they are weighted, but perhaps by a weight corresponding to the cup-shaped rubber piece about two inches in diameter this could be overcome. Very pure soft rubber would have to be used also as otherwise age and constant use will deteriorate it too quickly. 

Dynamometer. 
(268) Isaac Weiss, Brooklyn, N. Y., says: "I have an idea of a Dynamometer and Efficiency Instrument, which I know will work and believe it practical. It would like to know thru the columns of your magazine whether or not there is any demand or field for such an instrument." 

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.
"The object of the invention is to provide a new type of device by which the amount of power being transmitted thru shafting is measured without the possibility of any portion of the power transmitted thru the dynometer. Its use is to test the amount of power each machine in a large plant is using, and to find the most efficient speed to run machines. This information, I believe, is of great value in the daily operation of large plants using great power."

I have met the requirements of such instruments in a portable, direct-reading dynamometer of the capacity which occupies very little room on the shaft to be tested, takes a small amount of time to set in position for testing, and does not require the shutdown of any machine for testing.

A. If our correspondent has really produced such an instrument, we should think that the device would be of great value. Not knowing the full details we, of course, cannot give an intelligent answer. We would refer our correspondent to one of the patent attorneys.

Tail Lamp.

(267) John Hore, Sheridan, Ind., writes; "Would an automobile tail-light made in the form of a cored red-glass tube, be a good selling Auto Novelty? The light to be about three inches in width and length and one and three-quarters inches in thickness."

A. We are afraid that while this is a good idea, the authorities would not sanction the use of a Red Cross emblem of this kind on private vehicles. The cored glass would be too small to make for confusion, but this is merely our idea. Otherwise, we have no reason to doubt that it would be a patent that can be obtained.

THE MANIPULATION OF GLASS TUBING.

(Continued from page 395)

This may be all right and may give the required result functionally, but not mechanically, as any one who has handled a tube will such a construction knows, a break breaks very easily. The problem is to make such a constriction and have it strong as the original tube. This may be done very simply. Put the length of glass in a blow-pipe flame so that a portion about one inch wide is heated. Rotate the tube constantly to obtain a distribution of heat and while rotating gently push the tube TOGETHER instead of drawing it apart. This will cause the walls at this point to thicken. When the walls are quite thick, much thicker than the original walls, gently and firmly draw the tube out, and the resulting constriction will be as full as thick, or even thicker than the original tube.

ENLARGING THE DIAMETER OF A TUBE.

It is not so easy to enlarge a tube and keep the walls heavy at the same time. It is better to use heavy tubing and not make the enlargement too big. The entire success of blowing the glass in the heating of the tube. If one side of the tube is hotter than the other, naturally the enlargement will be one side. Also the enlarging of an argon pipe is sometimes too thin to support the operation. With only one blow pipe it is impossible to heat both sides at once so that if an enlargement is put on after once made, one side is sure to melt before the rest of it is heated, thus spoiling the symmetry of the bulb.

Heat the tube as for a construction, then when white hot remove from the flame and blow with a steady pressure on the open end, rotating the tube all the while. If you do not rotate the tube while blowing the force of gravity alone will make the resultant enlargement lose the shape of the bulb.

**Electrical Experimenter**

Cut a series of tubes slightly longer than the length desired. After they are cut end should be sealed in a flame and put aside. Next draw out the other end of each so that a tube with an opening of about one to two millimeters in diameter is on the end of each ampoule. Each ampoule will now be composed of the main portion which is to form the finished container, a narrow tube, and then a short untouched piece of tubing, which was used to hang on to while drawing out the tube. (See illustrations in Part L)

The ampoules may now be filled with the desired liquid. This may be done by using a fine hypodermic needle and syringe and inserting the needle point all the way down into the ampoule. But most experimenters do not happen to have a long needle hypodermic around their laboratory. So one is quickly made by drawing out a piece of tubing which will be small enough to reach into the ampoule and then fitting a rubber pipette bulb on the other end.

After the ampoules have been filled about three-quarters full they are sealed off by rapidly passing the narrow tube thru a very hot flame. The sides of this tube are very thin and will melt together almost instantly, and even when filled with an inflammable or volatile liquid, the sealing will take place so quickly that there will be no trouble in sealing the tube without heating the contents. One thing which must be observed, however, is that the ampoules must be kept in an upright position until the seal is cool, otherwise the cold liquid coming in contact with the hot glass will surely crack it. When cool the ampoules may be scratched with a file near the seal and put away in a drawer. When it is wished to open one of them the tip may be broken at the file mark, and its contents extracted.

**Uses of Sealing Wax in Glass Tubing Manipulation.**

Sealing wax is very valuable in working with glass tubing, as if applied correctly it will stick to glass firmly. In case of pieces of apparatus where one tube is to be sealed inside another, it is especially valuable as it is almost impossible for anyone but an experienced glass blower to seal one tube inside another. So it is necessary to use sealing wax to accomplish the same result. (See Fig. 6.) It has many disadvantages for chemical laboratories as there are numerous liquids which would dissolve it and render it useless. But for many purposes it is invaluable and should always be on the glass blowing bench.

**Duplication of Commercial Articles.**

When the need for a certain article made from glass comes up in the laboratory, do not buy it until you have carefully studied it and decide that you cannot possibly duplicate its itself. Commercial catalogs are invaluable for the purpose of giving the construction of many of these pieces of apparatus. With a little study you will find that most of the articles illustrated may be home-made with very little trouble. To illustrate the point, I made a $2500 Meinke wet plate de-calcifier, a jet vacuum pump, adapting the design to fit my raw materials, using the illustration in a catalog of a more expensive house as a guide. There were a number of changes, it is true, and it did not look as pretty, but when I came to calibrate the vacuum in terms of millimeters of mercury I found that I could exceed the vacuum claimed by the supply house. (See Fig. 7.) I now have both, and the Meinke pump besides costing less than 25 cents is stronger and works better than the "made in Germany" product, which cost $2.50. Try it.

**What Do You Know?**

Never mind how strong you are. The boss is looking for brains, not brawn.

It's a fine thing to be healthy and hard as nails, but when the boss wants a man for a big job, the kind that pays real money, it's what you know that counts.

Right now the Government and employers everywhere are looking for men with special training—men who can do some one thing well.

**How about you?** Are you ready for one of these positions? Have you an expert knowledge of any kind of work?

If you haven't special training, get it now! You can do it—in spare time—through the International Correspondence Schools. Pick the position you want in the work you like best and the I. C. S. will give you the training you need right in your own home—when you can afford it. You need never lose a day or a dollar from your present occupation.

More than two million have prepared for success in the I. C. S. way. Surely, what so many have done, you can do. The first step is making up your mind to do it. Get this coupon.

Franklin Institute, Dept. V102, Rochester, N. Y.
CHEMISTRY!

We present herewith to our friends our New E. I. Co. Chemical Laboratory which contains real chemicals and apparata to perform real chemical experiments. This outfit is not a toy, put up merely to amuse, but a practical laboratory set, with all the chemicals, apparata and reagents necessary to perform real work and to teach the beginner all the secrets of inorganic chemistry. With this outfit we give free a book containing a Treatise in Elementary Chemistry, useful data and recipes, and 100 instructive and amusing experiments.

THE E. I. CO. CHEMICAL LABORATORY

DESCRIPTION OF THE OUTFIT

It contains the following 44 chemicals:

<table>
<thead>
<tr>
<th>Ammonium Chloride</th>
<th>Ferric Sulphate</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alum</td>
<td>Nickel Sulphate</td>
</tr>
<tr>

THE MANIPULATION OF GLASS TUBING.
(Continued from page 423)
and see, after a little practice you will be able to fit up your laboratory with glass apparatus made in America, by yourself, which often is better and cheaper than the average commercial product.
(Conclusion.)

THE EINTHOVEN GALVANOMETER.
(Continued from page 391)
current flowing thru it. In order to obtain this deflection it is necessary to carefully regulate the tension of the string and the intensity of the field flux, which is controlled by the current flow in the galvanometer circuit with the aid of the rheostat, R. This requires a great deal of patience and care until the instrument is finally adjusted to this sensitivity. It is found that the string will be deflected a maximum at a given magnetic flux intensity, and if the current is further increased until the magnetic saturation of the cores takes place, the sensitivity of the instrument is decreased greatly; so it is advisable to take precaution in adjusting the current flow to the electric-magnets. It was also found that as soon as the tension of the string was altered at a given magnetic flux adjustment, that its sensitivity was impaired. Therefore, every time the tension of the string is varied, a corresponding change of the magnetic flux intensity in order to keep the instrument at a maximum sensitivity point.

The Einthoven galvanometer was utilizing great success in conjunction with radio-communication for recording received signals. It is the only instrument ever devised for receiving directly telegraphic messages sent by radio at speeds ranging from sixty to one hundred words per minute. This is accomplished by photographing the impulses received by the galvanometer string, which are projected upon a moving photographic film. The arrangement shown in Fig. 21 is used to accomplish this. This standard radio receiving circuit for the reception of continuous long wave lengths is used, since the undamped transmitters with high speed automatic keys are utilized for the purpose. A is the antenna connected to the primary of the induction coupler L C, and back thru the ground, G. The secondary S, of the inductive coupling is shunted with a variable condenser, V C, and linked to a vacuum tube detector A, the grid and wing circuits being electro-magnetically coupled to each other by means of the feed-back circuit, F. This is done to make the tube regenerative, thus increasing the undamped oscillations from the distant transmitter by beat reception. The audio-frequency circuit contains the telephone receivers, T, and the Einthoven galvanometer, each of which may be used merely by throwing switch, S W, in the respective contacts.

To record or photograph the incoming signals, the operator has but to listen to the telephone receiver, and as soon as he receives the proper transmitting station, he switches S W to the galvanometer terminal, which causes the string W to be displaced in accordance with the signals. Thus the string images are projected thru the magnifying and projecting telescope, T, to the moving film contained in a perfectly light-proof box. The light is derived from an incandescent lamp L, with reflector, R. This light is then condensed to a single beam by means of a condensing lens, L, and then permitted to fall on the string, W. The developing and fixing mixture are placed in the lower compartment of the photographic container, and as the film is moved at a constant and definite speed (Continued on page 427)

THE EINTHOVEN GALVANOMETER.

(Continued from page 425)

velocity by two rollers driven by a motor, the photographer portion of the film is developed and fixed, and its message transmitted at the moment of its leaving the fixing tank. The process is very rapid and it is the only means utilized by the large radio companies, especially those having a great deal of traffic.

Not only is this instrument utilized in radio telegraphy, but it has assumed the most important role in the art of transmitting photographs over electrical circuits. It may be mentioned that whenever a very sensitive galvanometer is used, especially for recording high periodicity impulses, the Einthoven galvanometer is the only one that will meet the requirements.

(Continued from page 403)

SPECTROSCOPIC METHODS AND THE PRODUCTION OF SPECTRA.

points should be as large as the spark will permit.

The apparatus can be easily and hand-somely mounted as the arrangement shown in Fig. 2. The four small screws are screwed on underneath the tube. The tube is held by two bands of tin or copper. These are clamped to the tube by means of two small bolts and the ends screwed to the uprights. The electrical connections are made by pouring some mercury into the tube "P," and filling the tube "X," which is glass, bent and fastened to the board by a strip of metal. Into one end leads the platinum wire from "C," and into the other lead the wires from "D.

If the apparatus is intended to be connected direct to the spark coil, the wires from the coil may be directly inserted into the mercury in the two tubes, but it is better to fix two binding posts in the base and connect the coil to these. In this case the wires are fastened in the binding posts to the mercury should be iron, as copper will amalgamate with the mercury and cause trouble.

The apparatus is now ready for use. A solution of the substance to be examined is placed into "A," preferably with a pipette, till it just reaches the top of the glass tube "C." The current is now turned on. The liquid is drawn by the capillary attraction of the glass to the jet, and each spark vaporizes a tiny portion.

Both the level of the solution, the hole in the jet, and the position of the platinum wire may have to be adjusted before the apparatus will work satisfactorily. The chief advantages of this method are:-(1) Ease of working. (2) Small amounts of material can be used. Many materials that will not vaporize in the Bunsen flame will vaporize in the spark, and also many materials that give a spectrum in the Bunsen, but not in the spark, will give many more lines. (4) The supply is practically inexhaustible.

ELECTRICAL PHYSICS.

(Continued from page 386)

EXPERIMENTAL PHYSICS.

ever, the coil is held stationary over the magnetic field, no motion will be observed. i.e., no current flows. If the coil is driven up past the pole the needle will deflect in the opposite direction. If we alternately thrust down and draw up the coil it is obvious that an alternating current will result. By use of a commutator this current can be converted into direct current (the commutator is a device for reversing the current alternately when each change in direction occurs; the two reversals being equivalent to no reversal at all). We may now add to the theoretical discussion by the obvious principle that when a conductor moves in a magnetic field so as to cut the lines of force of the field, a current is induced in the conductor. The right-hand rule is an excellent guide for determining the direction of the induced current. Bend the thumb and the index finger of the right hand at right angles to each other. Point the thumb in the direction of the motion of the conductor, the first finger in the direction of the lines of force of the magnetic field; the central finger indicates the direction of the current. In the modern dynamo, of course, instead of hand power, steam or water power is used. The induced current and also the necessary rotation is usually much simpler and requiring less work, the advantage of other advantages, the coil is turned by the water. (These rules are also called the dynamo and motor rules respectively.)

EXPERIMENT 96-—Wind about 500 turns of number 28 insulated copper wire around the end of a 14-inch iron core and connect to a galvanometer such as shown in experiment 96. Wrap about the same number of turns about another portion of the core and connect to several cells. When the circuit is closed the deflection of the galvanometer will indicate the passage of a current thru the coil a in spite of the fact that the alternations are not in the metron of a. When the circuit is opened, an equal but opposite deflection will indicate the flowing of an equal current in the opposite direction. This experiment illustrates the principle of the induction coil and the transformer. The coil b is called the primary and coil a the secondary. Counting the lines of force to appear inside of a (magnetising the space inside of a) caused an induced current to flow thru the coil. Deflection of the galvanometer shows the current. Stated more compactly and correctly, any change in the lines of force of which thread a coil produces an induced current in the coil. In the alternating current transformer, the number of lines of force changes because the magnetising force is always changing. In the direct current transformer (induction coil) the number of lines of force changes because of the position of the core, and therefore of the interrupter of the form described in experiment 94.

In figure 88-B, c denotes a soft iron core composed of a bundle of soft iron wires; p is a primary coil wrapped around this core and consists of about 200 turns of number 16 insulated copper wire; connected to the

A CHEMIST of the Future

Every boy who plays with Chemcraft now is gaining knowledge that will be of greatest value to him when he grows up, and there isn’t anything more interesting than working Chemcraft experiments.

Think of being able to make soap and ink, of testing your water supply and foods, and there are dozens of wonderful magic changes that will completely mystify your friends.

Chemcraft is recommended by leading chemists, government officials and professors in leading schools and colleges. It is scientifically correct.

Chemcraft No. 1 sells for $1.25
West of the Mississippi and Canada, $1.50
Chemcraft No. 2 sells for $2.50
West of the Mississippi and Canada, $3.00
Chemcraft No. 3 sells for $5.00

battery circuit by contact point on the end of screw d, a secondary coil 1 is wrapped around the primary and consisting of about 50,000 turns of number 36 insulated copper wire connected to the terminal point (spark gap) i, and a spring hammer f for making and breaking the primary circuit. Just as in the case of the bell an intermittent current passes thru the primary, hence inducing a current in the secondary. The rate at which the lines of force are cut determines the voltage of the current; also since the number of turns of the secondary is so much greater than that of the primary, the effect is similar to having the same number of turns but more lines of force cut, and hence the induced voltage is tremendously greater than that passing in the primary circuit.

The subject of electricity is a vast one and because of its great commercial value is by far the most important division of Physics. In devoting only three lessons to it the author had to omit details and discuss only the fundamentals of the fundamentals. His hope is that a desire for further light on the subject has been awakened in the reader.

TO BE CONTINUED.

POPULAR ASTRONOMY.
(Continued from page 383)

...to be considerably less than our own, is familiar to every one. A second theory upheld convincingly by Prof. W. H. Pickering is the one of aerial deposition. The more prominent canals, according to this theory, are marshy strips of vegetation, lying in the path of water-laden air currents blowing from the vicinity of the melting polar cap toward the equatorial regions and depositing moisture along their paths during the Martian night. The absence of dense clouds in the planet's atmosphere and the amount of detail visible in the surface markings at a distance that is never less than thirty-five million miles show that the atmosphere of Mars is very rare. The daily range of temperature must therefore be very great, the days being extremely hot and the nights extremely cold. Much moisture would, therefore, be deposited at night.

In regard to the appearance of the broader and more conspicuous canals, that are comparatively few in number, Prof. Lowell stated that ninety per cent of them were either straight lines or followed the arcs of great circles, while Prof. Pickering declares that many of them are quite distinctly curved and attributes this curvature to the deflection of the air currents that feed the canals or marshes, due partly to friction with the atmosphere and partly to the effect of the rotation of the planet on its axis. He computes from the radius of curvature of several of these canals at a recent opposition the velocity of the storms that feed them and arrives at a value for the minimum pressure of the atmosphere of 7.5 inches of mercury or less than one-quarter of a terrestrial atmosphere. The corresponding temperature of boiling water on Mars he, therefore, finds to be 150°F.

It has also been noted in past oppositions of Mars that certain canals occasionally shift their positions noticeably both in latitude and longitude by the amount of several hundred miles.

A number of observers of the broader canals have criticized their representation as fine, straight lines, artificial in appearance, claiming that they appear rather—to use the words of one observer—as "soft streams of dusky material with frequent condensations."

Tobacco Habit Banished In 48 to 72 Hours

Immediate Results

Trying to quit the tobacco habit unaided is a losing fight against heavy odds, and means a serious shock to your nervous system. So don't try it! Make the tobacco habit quit you. It will quit you if you will just take Tobacco Redeemer according to directions.

It doesn't make a particle of difference whether you've been a user of tobacco for a single month or 50 years, or how much you use, or in what form you use it. Whether you smoke cigars, cigarettes, pipe, chew plug or fine cut or use snuff—Tobacco Redeemer will positively remove all craving for tobacco in any form in from 48 to 72 hours. Your tobacco craving will begin to decrease after the very first dose—there's no long waiting for results.

Tobacco Redeemer contains no habit-forming drugs of any kind and is the most marvelously quick, absolutely scientific and thoroughly reliable remedy for the tobacco habit.

Not a Substitute

Tobacco Redeemer is in no sense a substitute for tobacco, but is a radical, efficient treatment. After finishing the treatment you have absolutely no desire to use tobacco again or to continue the use of the remedy. It quiets the nerves, and will make you feel better in every way. If you really want to quit the tobacco habit—get rid of it so completely that when you see others using it, it will not awaken the slightest desire in you—you should at once begin a course of Tobacco Redeemer treatment for the habit.

Results Absolutely Guaranteed

A single trial will convince the most skeptical. Our legal, binding, money-back guarantee goes with each full treatment. If Tobacco Redeemer fails to banish the tobacco habit when taken according to the plain and easy directions, your money will be cheerfully refunded upon demand.

Let Us Send You Convincing Proof

If you're a slave of the tobacco habit and want to find a sure, quick way of quitting 'for keeps' you owe it to yourself and to your family to mail the coupon below or send your name and address on a postal and receive our free booklet on the deadly effect of tobacco on the human system, and positive proof that Tobacco Redeemer will quickly free you from the habit.

ELECTRICITY!

Here's just the book on Electricity that you need to answer your many questions— to solve your knotty problems— to teach you new kinds, to be your memory for tables, rules, formulas and other Electrical and
Mechanical facts that some people try to learn by rote and others never learn. With this "Little Giant" I. C. S. Engineers Handbook in your pocket, you'll have your work bench, drawing table or desk, or hour or day need not be lost.

"digg ing up" some forgotten rule, some un-
familiar fact; you'll just turn to the very con-
plete index and get it all at a jiffy. Just a few of the subjects treated are:

Electricity and Magnetism; Electrical Sym-
bols; Batteries; Circuits; Magnets; Direct and
Alternating Currents; Dynamoelectric Mot-
avs; Transformers; Telephonic; Telegraphic;
Shaping; Electroplating; Electrical Measure-
ments; Motors; Arc and Incandescent Lamps; Mercury Arc Lamps; Artificial Light; Insulation; Electric Cars; Single and Multi-
ple-Pole Control; Transformers; Tables of Wires; Sizes, Capacities, etc.; Mathematical Rules; Formulas, Symbols, Tables of Constants, Equivalents, Roots, Powers, Re-
ciprocal Numbers; Area; Volumes; Weights; Chemistry; Properties of Metals; Principles of Mechanism; First Aid etc.
The Electrical Engineer's Handbook is one of 12 I. C. S. Handbooks covering 27 technical, Scientific and Commer-
cial subjects. It is an indispensable guide and helps you understand everything electrical. Read the reviews! The book is really an investment, a fact that you will find exciting. With such a price and generous returns, you would be a fool to pass it by. For a jiffy, write for free copy.

No Risk Money-Back Offer!
The price of the handsome I. C. S. Handbook, of which more than 2,000 have been sold and are in great de-

Big Powerful MAGNET

Flatest iron steel magnet, 5 inches thick, 5 inches broad, 5 inches long. Lifts about 3 pounds. Good for household service. Also for scientific, useful and enables
you to perform scientific tests, ex-

electricity, etc. etc. Send 10 cents for second magnet.

ELECTRIC GENERATORS

We also have a number of electric generators in stock, which will be disposed of at

Watson Electric Co.
Dept. 210, Gas Bldg., Chicago
THE "LITTLE PET"

is unquestionably the engine you have always wanted. Ideal for running small electric motors, phonographs, for charging storage batteries, electroplating for the laboratory, for the workshop, drive bench lathe, grinders, saw, washing machine, etc.

Operates on either gaso-lene or City gas.

Coil built into engine, counterbalanced and all parts safety housed. Ready to run when you unpack it, only battery to be connected. Any speed from 300 to 1400 R.P.M. can be had instantly, while engine is running.

Step on foot pedal to start engine. Automatic oiling, no grease cups, an ideal home motor safe and dependable, will last for years. Cost to run 175 cents per hour. Engine has 2" bore and 2" stroke. Given over 75 H.P. Weight 60 lbs.

High Frequency Bargains

In taking our inventory we found over 200 Violet-Ray machines of all makes. We selected 100 of the best machines, which we thoroughly overhauled in our factory making them better than new. Many of these machines cost over $40.00.

We have placed all these instruments in two groups and are disposing of them for the ridiculously low price of $9.75 and $12.50.

How to secure one of these machines

Send only 50 cents to pay express charges and we shall send you one of these instruments by express for your examination. This amount will be deducted from total cost of machine. You need not accept the machine.

Send at once for we shall send the best machines out first and the quicker you send in your order, the better machine you will get.

We shall also send our beautiful booklet "Violetta" describing the many uses for the high-frequency current. Write us before purchasing any kind of Violet-Ray Machine.

BLEADON-DUN CO., 11-17 S. DESPLAINE ST. Dept. 2A CHICAGO

"Treat 'Em Ruff Boys" is the only line that fits in stage five, when the Yanks come to grips with the Huns in their own trenches. Here the standing and creeping barrages combine and advance to the rear, and finally, if the Huns do not surrender, a counter battery is planted to prevent their retreat, and also the bringing up of reserve troops and supplies, as much as possible, in stage six, for enemy counter-barrage. This is in a good luck with a counter barrage and this is liable to happen at any point in the previous stages, all depending on the strength of the enemy, tackled by the German commander (the counter barrage is indicated by the curved line of iron crosses) but, of course, the shells fired by the German guns are not quite so elaborate in shape; ask "Sammy"—he knows. The effect of the counter barrage is sometimes quite disastrous, unless the troops are able to dig in and make use of the underground galleries and dug-outs which they have captured until their own guns can silence the counter-barrage artillery, which may be several miles in the rear in some cases and well camouflaged. Another effect of the counter barrage is seen as the digging up of more than one or two waves of attacking infantry.

It was found, however, that even as effect as the barrage proved, there were still loop-holes by which the "Boche" could make his escape. For instance, he awakened to the fact that if he could withstand the shell-fire until the barrage had reached and past his own front trench, that he could then scamper around the "side" ends of the barrage "fire-curtain," out of the barrage to another escape to his second or third line trenches and dug-outs. But the Allied artillery experts soon got on to this cunning maneuver, and now they make use of what is termed by an artilleryman a "box barrage." This is shown in the accompanying illustration, and as will be seen, a number of the barrage-cannon are employed at certain intervals to create a cut-off wall of shell fire, as at A, A.

Some of the wonders and mysteries of modern artillery barrage fire are unmasked in a very excellent lecture recently given before the Washington Academy of Sciences by Major General John Headlam in charge of the British Artillery Mission in this country. General Headlam in his lecture, which was entitled "Developments in Artillery During the War," pointed out many important and highly interesting features of present day artillery practice, and in line with the foregoing discussion he has considerable to say concerning the how and why of barrage fire, particularly as related to regular artillery bombardments and the general factors related thereto, such as the methods of observation, the manner of allowing for loss in range due to multifarious factors such as wind velocity, humidity, air pressure, gun erosion, etc., etc.

The accompanying battle-field panorama shows in a vivid manner the general arrangement for carrying out an artillery barrage and the outstanding features of such an offensive, notably the numerous and highly diversified means of gathering the important information essential to insure the hair-line accuracy demanded in such an artillery operation.

In the first place it is interesting to note that the artillery, even for carrying out a barrage offensive, is not always situated as far back from the front line trenches as we are wont to imagine, for as General Headlam says,—"But, as a matter of fact, just as this war has seen the revival of hand-to-hand fighting with the bayonet and the rifle butt, so it has seen guns pushed into closer ranges. On many occasions I have known individual field guns put within two hundred yards of the enemy's trenches."
With time, ingenuity and courage, a gun can be gotten almost anywhere, and the effect of its fire at such ranges is very marked while its presence affords immense discouragement. One case in which I may mention, where a gun had to be brought up over the open, and it was moved at night by stages and carried by the church in high festivities. The gunners who carried the gun, would be trained to drop it on the gun when a "flare" went up, and the gun was supposed to be sighted at a range of seventy yards in nine minutes; completely destroying its objective, and then they returned to the gun. If the gun was not in the hands of a trained gunner, and the cartridge was of a different kind than that used in the gun, the shot would be fired and the gun destroyed.

General Headlam covers a number of interesting points, and then comes to the problem of the "flame" gun, which is said to be a success, and next we must make to keep lots together. One of the things that must be observed by the artilleryman is the weight of the shell, and the various lots of shells are carefully examined, checked, and marked for weight. The next thing the artilleryman has to think of is the hand of his gun, or rather how hard it has lived, for as a gun wears, its accuracy and its range fall off. The former cannot be calculated, but the latter cannot be calculated; and the loss of muzzle velocity in each gun must be found and allowed for. This is what we call "calibration," and the gun must be re-calibrated and re-checked every time it is used, and in a howitzer with each charge. These problems are usually carried out on the front, because we prefer whenever possible, that every shell should have at any rate a chance of killing a German. To enable it to be done the topographical sections provide the gun batteries with maps, carefully mounted, so as to avoid errors due to shrinkage or warping, and showing accurately not only the positions of the guns and their ammunition positions, but also such datum points as may be desired inside the enemy's lines.

Then we have the error of the day. "Having written on the known to artillery science, the errors of the guns, a battery commander has next to think of the error of the day, or rather, of the moment," says General Headlam. "He must ascertain and allow for the height of the barometer, the temperature of the air, the temperature of the gun, and the force and direction of the wind for a given time of flight, and here he must depend on his scientific friend "Meteor" in the nearest meteorological station, and the files of the steamships, which sends to him every few hours cryptic telegrams giving all essential facts. Then when we know the hand of the gun, the correction of the deflection and the calculation to be performed and carried out by artillery officers seem quite methodical and well settled, yet they are not always so easy to apply in the field by any means, and also they are sometimes fraught with considerable danger, especially where tests are being made with actual shell and blank cartridges, and with the observers located in shell holes or front line trenches. General Headlam mentions that the best battery commanders were killed by a shell from his own battery while he was conducting the fire from a trench and from which he had cleared the enemy, and then for the reason that the artillery officer or gunner has misjudged his fire.

The Artillery Barrage — How It Works.

(Continued from page 433)

zone for all of the shells from a series of rounds fired at the same time and elevation will not fall on the same spot, but will cover a rectangle varying in size with the gun and the rounds.

Not only is the artillery officer confronted with an amazing amount of mathematical calculations to be performed almost instantaneously, as well as very accurately, but he must see to it that his arrangements for the observation of shell fire is composed of a large number of observers, as shown in the accompanying illustration, or where the observers are in aeroplanes — for the enemy, especially in a heavy counter-offensive, has an irritating habit of “dropping” these observation planes and balloons (blimps, as they are called) with a well directed shell on a large number of objectives.

In most cases artillery observation officers are sent forward with advancing infantry, and batteries are stationed near the front line trenches in shell holes or other advantageous points. The aeroplane observers communicate their findings by wireless telephonic lines handled under the supervision of the Signal Corps, and these lines of communication must be maintained in constant working order. An observer, for example, specially trained in the use of aerial navigation, will be registered the position of any gun that is foolish enough to open fire from an insufficiently masked position when the clouds are dark behind it. Then comes the sound-ranger, who, with his delicate instruments, registers the discharge of the enemy’s gun.

One of the latest developments in artillery is the “aerial barrage,” which comes within the realm of anti-aircraft gunnery. This is one of the most remarkable and as yet not very well-known branches of gunnery, and one in which there is a great opportunity for students of such work. It has often been said that it takes approximately a thousand shells to bring down or “bag” an enemy plane, even at a fairly low height, and then in most cases, the plane does not come down at all. As General Headlam says, “If you think that the results obtained have been small, that with all the expenditure of time and material devoted to the present enormous operation of aeroplane observation to bring ‘bag’ is insignificant, you must remember the difficulties of the task. An aeroplane has a life of only about 30 to 40 minutes, even if the weather is clear, while the shell is in the air, and I leave it to the sportsmen among you to say how many ducks they would pick up under such conditions.”

LEARN TELEGRAPHY QUICKER—EASIER

Adjustable Buzzer Practice Set

 Quickly Gives You Speed — No Tools Needed — A Touch of Your Finger Adjusts It

This practice set enables the student to learn telegraphy more or less immediately. In shorter time than ever before thought possible. A touch of your finger on a small screw gives any pitch desired to the BUZZER. Especially designed to save very clear round—of exceptionally high pitch, true on ONE DRY CELL. The adjustment of the BUZZER to any pitch is made without breaking of any kind—simply by the thumb screw.

The greatest improvement in practice sets ever made—superior to any on the market. Beautifully made; mounted on substantial base.

U. S. AIRPLANE Mail Service

Started May 15, 1918

marks the real beginning of commercial aviation. Uncle Sam is carrying mail every day between New York, Washington and Philadelphia and the end of the war will make possible the extension of air-plane mail delivery to all parts of the country. As fast as machines can be built they will be put to work carrying freight and passengers. But the demands of commerce must wait. Every man who knows, not merely how to make one small part of an airplane, but who has studied and learned the scientific principles of design and construction is needed RIGHT NOW to help win the war.

More Men Needed AVIATION

Wonderful salaries are being paid to trained experts in airplane building, airplane assembling, repairing and adjusting. Here is an easy road to promotion or to a splendid paying position in the private employ of one of the scores of airplane manufacturing companies. We have more calls for men than we can supply. Never has any industry offered so many golden opportunities for ambitious men. Make it your business to investigate first before you decide. But don’t wait to send for full information.

FREE NEW BOOK--“OPPORTUNITIES IN THE AIR-PLANE INDUSTRY.”

Just published and mailed free on request—the first complete story of the recent remarkable development of the airplane manufacturing business and the wonderful future it holds for you. Get a copy and read it. Let your friends read it.

Mail Coupon--QUICK

SIMPLIFIED

Stenography

READ THESE AMAZING — absolutely logical — FACTS

ABOUT K. I. SHORTHAND. This is a simplified system of

stenography easily learned in a few hours, after which speed in

writing comes with ordinary usage.

The old systems of shorthand are all right but are unnecessary for most of the practical purposes of

life. By comparison you might solve a problem, using logarithms, that could be done more quickly and

easily by simple arithmetic. In certain countries, a knowledge of engineering gained by intensive study for

two or three terms is necessary to entitle a person to operate a motor boat, yet here in America, even a

girl or boy is able to run such a boat after a few hours of study and practice. Similarly with stenogra-

phy—the simplified K. I. Shorthand enables a person, young or old, to sweep aside old-school restrictions

and do practical stenography in an amazingly short time.

No need of a teacher to stand over you. K. I. Shorthand comes in books—complete—easy to learn in spare moments whenever you are.

The system of K. I. Shorthand is the original and can be obtained solely from King Institute at the exceptionally low cost of FIVE DOLLARS.

Nothing further to pay and special instruction given without charge, by correspondence, if needed after you have obtained the Course of

Instruction. No such privilege given with any other

low cost method.

Try for Government work

WHY

SO EASY TO LEARN

You can set down words in K. I. Shorthand as fast as they are spoken, or as rapidly as your mind logically acts when you are thinking out an essay, speech, directions, etc.

You can read your own notes—transcribe everything—word for word, accurately, weeks, months or years afterward. Your assistant can quickly learn to read and typewrite your notes.

One reason why K. I. Shorthand is so easily learned—and never forgotten—is that you are not (like the extensive, expensive systems) compelled to do light or heavy shading; or write in special positions above, or on below lines.

All superfluous technicalities eliminated; they are unnecessary for all ordinary purposes as is the knowledge of trignometry or ancient Greek language.

In 5 Evenings

 SO EASY TO LEARN

Try These K. I. Shortcuts

Association

This word takes 34 pen movements in ordinary writing—only 2 in K. I. Shorthand. See how many times you can write it while your friend writes in the usual way.

Notwithstanding

Takes 54 movements in longhand; only 3 in K. I. Shorthand. The whole method is surprisingly easy to learn.

Representative

Takes 41 movements in longhand; only 2 in K. I. Shorthand. Learners, all ages, are delighted with their quickly attained speed.

So, here is a circular

act

ng or ing

act

TO WRITE "ACTING" IN THE ORDINARY WAY REQUIRES 2 PEN MOVEMENTS—ONLY 4 IN THE PERFECTED AND SIMPLIFIED K. I. SHORTHAND.

How To Order

Send $5.00 in full payment. Or, more conveniently, to save time—lease $1.00 new and you may pay $5.00 after 10 days.

To readers of Electrical Experimenter

The photo here shown is of Naval Radio Operator E. D. Sefrowici, who acquired the principles of K. I. Shorthand in a few hours, and soon became able to use it in his work as a radio service operator. These are many written of K. I. Shorthand in the Navy, and have obtained the course. The Commander of the Base of Naval Radio Service in

Army and Navy send a handsome testimonial in K. I. Shorthand, and the Miami Police Department have complimented the system for its ability to enable officers to take notes for all purposes, and carry in their pockets a correspondance course of dictation without extra charge. The total cost is five dollars for a K. I. Shorthand system—no more—and we guarantee satisfaction or will refund your money.

'LEARN BY DOING'

The Only Way to Learn Electricity

The only way you can become an expert is by doing the very work under competent instructors, which you will be called upon to do later on. In other words, learn by doing. That is the method of the New York Electrical School.

Five minutes of actual practice properly directed is worth more to a man than years and years of book study. Indeed, Actual Practice is the only training of value, and graduates of New York Electrical School have proved themselves to be the only men that are fully qualified to satisfy EVERY demand of the Electrical Profession.

At this "Learn by Doing" School a man acquires the art of Electrical Drafting; the best business method and experience in Electrical Contracting, together with the skill to install, operate and maintain all systems for producing, transmitting and using electricity. A school for Old and Young. Individual instruction.

No previous knowledge of electricity, mechanics or mathematics is necessary to take this electrical course. You can begin the course now and by steady application prepare yourself in a short time. You will be taught by practical electrical experts with actual apparatus, under actual conditions. 5,000 of our students are today successful Electricians. Come in and read their enthusiastic letters. Let us explain this course to you in person. If you can't call, send now for 64-page book—it's FREE to you.

New York Electrical School

Every Electrical Man Wants These Books
and we ship them for your inspection FREE

Flexible Covers
Handy Pocket-Size Volumes

Just what you need to know to succeed in ELECTRICITY

E VERY electrician, every engineer, every mechanic should know about these wonderfully helpful instructive books, which give in plain words a complete working knowledge of electrical engineering in all its phases.

You run into some new electrical problem almost every day. The information you need to help you in your everyday work is in the Hawkins Guides.

These books place electricity at your finger tips. They cover every imaginable subject, principle, theory, problems, proofs and way of doing things electrically. Every subject is indexed so that you can turn right to it. They are a study course and a reference guide all in one, written in plain everyday language so that anyone—all who need to know—will find full of up-to-the-minute electrical knowledge.

The guides are a complete course in electrical engineering. They will help you in every detail of the day's electrical work. You can't ask an electrical question that Hawkins Guides can't answer.

Pocket-Size Flexible Covers

Send No Money

It will cost you nothing to receive these books—to look them over—and ask them all the questions you can think of—and them in your work—study them—pick up some information that will increase your earning ability. We will ship you the outlook of 15 volumes entirely FREE

This is a sign of our confidence in the guides. We guarantee you satisfaction, or your money back. Keep them for seven days and if you do not decide that you can't get ahead without them, return them to us and owe nothing.

When you decide to keep them, you only have to pay $1.00 down and remit the balance of $9.00 on the easy payment of 10c a month till paid for.

Use this coupon to get the books. It will pay you many times over.

"Don't tell me you never had a chance!"

"Four years ago you and I worked at the same bench. We were both discontented. Remember the noon we saw the International Correspondence Schools' advertisement? That woke me up. I realized that to get ahead I needed special training, and I decided to let the I.C.S. help me. When I marked the coupon I asked you to sign with me. You said: 'Aw, forget it!'

"I made the most of my opportunity and have been climbing ever since. You had the same chance I had, but you turned it down. No, Jim, you can't expect more money until you've trained yourself to handle bigger work."

There are lots of "Jims" in the world—in stores, factories, offices, everywhere. Are you one of them? Wake up! Every time you see an I.C.S. coupon your chance is staring you in the face. Don't turn it down.

Right now over one hundred thousand men are preparing themselves for bigger jobs and better pay through I.C.S. Courses.

You can join them and get in line for promotion.

Mark and Mail This Coupon and Find Out How

Reports on 27,000 typical I.C.S. students show
14,900 now receiving $1500 a year or more;
2451 receiving $2500 or more; 413 receiving
$5000 or more; 20 receiving $10,000 or more;
and 8 with annual incomes of $25,000 or more.

WHAT OTHERS HAVE DONE YOU CAN DO"

Thousands of skilled Electricians are needed. The demand is becoming more urgent every day. The Government is employing everyone they can get which is causing a great scarcity throughout the country and big salaries are being paid everywhere. Right now is your big opportunity. Make up your mind now to prepare for one of these big jobs and then get here as quick as you can for your training.

**Earn $100.00 To $300.00 A Month**

In the Electrical business. Come here where you will be trained in these great $100,000 shops. Experts show you everything and you learn right on the actual apparatus. You work on everything from the simple bell to the mighty motors, generators, electric locomotives, dynamos, switchboards, power plants, everything to make you a master electrician. We have thousands of successful graduates. Just as soon as you have finished we assist you to a good position. We now have more positions than we can fill. Think of it.

**Prepare To Serve Your Country**

War Demands Have Taken Thousands of Men from this Profession. Men Must be Trained to Fill their Places. Prepare Now for a Big Paying Position.

These courses are thorough, short and practical. All instruction given on the actual equipment. Each man is trained individually and stays until thoroughly trained. Start any time—day and evening classes.

Our graduates are in great demand. We are continually receiving letters, telegrams, and telephone calls from contractors, manufacturing firms, etc., seeking our graduates to fill responsible positions. We have now more positions than we can fill and the demand is steadily growing. Every comfort is given our students while here. They live in comfortable homes in the most beautiful section of Chicago—on the lake.

**LEARN DRAFTING**

Skilled Draftsmen are always in demand. Our courses are thorough—short—practical, preparing a man fully to hold a position of responsibility. We have more positions than we can fill. We also have thorough practical courses in Plumbing and Heating and Motion Picture Operating.

**EARN YOUR WAY**

Many students earn a large part of their living expenses by doing a little work in their spare time. Our employment department furnishes these positions without charge.

Please send at once your big Free Book—I am interested in:

ELECTRICITY
AS EXPERTS KNOW IT

Learn electricity as you would in actual PRACTICE—in accordance with the methods employed by the highest paid electrical experts in America. The New McGraw-Hill Library of Practical Electricity contains the actual working facts which you need in order to succeed in the electrical field. Terrell Croft, formerly with the Westinghouse Company, makes the conquest easy for you.

A New Standard in Electrical Literature
The New Library of Practical Electricity by Terrell Croft marks a new era in electrical literature. The great field of electrical engineering, with its limitless possibilities of earning power, is brought to you in a form that makes success easy. The Library is a creation—an achievement that is without parallel in technical literature, because it sticks to actual practice throughout its 2560 pages.

$2
per month
starts
you to
bigger pay

(CROFT'S NEW LIBRARY OF PRACTICAL ELECTRICITY—8 VOLS.)

Now is the time to master Electricity—Now is the time to prepare for a high salary

Not one cent in advance—Just the coupon

Examine this new Library for ten full days without expense. Find out for yourself why it is now taking the lead in electrical book sales in America. Use the books as you see fit for ten days. Look at the hundreds of illustrations that clear up all the mysteries in electrical practice. Stick a couple of the volumes in your pockets, and refer to them during the way. Figure out in an instant the problems that have hitherto taken hours.

Then send us $2 per month for eight months, or return the set entirely at our expense. You risk nothing by returning the attached coupon.

ACT NOW

McGraw-Hill Book Co., Inc.
239 West 39th Street, New York, N.Y.

Old books won't do. Amateurish books won't do. Books compiled by "desk authors" or men with no practical experience will not serve your purpose.

Practical books are easiest mastered. Practical books, written by practical men, teach you accurately and rapidly. There is nothing in the Croft Library which you cannot understand. Terrell Croft tells you the secrets of success in electricity in plain words, figures and illustrations. Nothing is left to the imagination. There is no guesswork. There is no theory or higher mathematics.

Send now for these eight volumes. No matter how many books on electricity you possess, you are unprepared until you take advantage of this free examination privilege. No matter whether you are beginner or expert, these books will show you the clear road to success. Inspection will prove this.

You benefit by mentioning the "Electrical Experimenter" when writing to advertisers.
W E have pointed out on various occasions in these columns the criminal waste that daily occurs when we convert coal into electric light. We have shown that when coal is burned only one-half of 1 per cent of the actual energy stored up in the coal is converted into radiant light—the other 99½ per cent goes up out of it where no heat is actually wanted or required. The great problem of the century is heatless light, or at least an approach toward it.

All our efforts in developing incandescent lamps or arc lamps are in the wrong direction. While we have made trifling progress from the old carbon filament lamp to the up-to-date Tungsten lamp, the progress as far as wasted energy is concerned is more than trifling; it only amounts to a very small fraction of one per cent.

The arc lamp which is very much more efficient, giving infinitely more light in proportion to the Tungsten lamp, can not, of course, be used in a small room, as it gives more light than wanted, and for that reason is impractical. The other electrical devices which are still more economical, such as for instance the Cooper Hewitt mercury lamp, which may be worn around a modern photographic studio, or the Moore lamp, which is a sort of Geissler tube giving a soft, pink light, are excellent for their purpose, but neither of these are flexible enough where only 30 to 50 candle-power are required.

What we need is something similar to our present-day electric light globes, but such a device must not have an incandescent filament. What this future invention, which is surely coming, will be, we do not know and the best we can do is to make a fair guess.

In Nature we find several light sources that may be termed “cold,” aloha in reality most of them are not. Take, for instance, the Firefly (Luciola), whose light at one time was thought to be of an electrical nature. Recent investigations have shown that the light is produced by the burning of the oxygen in a certain peculiar manner inherent in the firefly’s photogenic cells. While, of course, not actually cold light, it comes as close to cold illumination as is imaginable.

Then there is a certain species of deep-sea fish—Lantern Fish—who attract the prey by a brilliant light shift from their photophores. In this case, the luminosity is known to be of a phosphorescent origin, which, strictly speaking, is not cold either, but for practical purposes comes close to it. Then will o’ the Wisp, as well as the luminous mushroom fall in the same category, their light simply being due to burning of oxygen.

Electricity at high pressures is also known to give out certain light effects, as, for instance, a highly charged Tesla coil; but this light, if anything, is more expensive than that obtained by means of an incandescent lamp. The next following, we have the high tension Tesla vacuum lamp, which gives forth a brilliant and also cold light. Due to the very high potential currents that are necessary to produce this light, it has so far not been exploited commercially, although it deserves it.

Perhaps some inventor will devise a sort of combination Cooper Hewitt-Moore gas lamp, which, instead of a filament, have only hundreds of feet of very fine glass tubing all coiled up inside of our present day lamp bulb. Then by introducing a suitable gas into this fine tubing, which, of course, must be of a fair conductivity, we may produce some sort of an economic lamp bulb, and, while this light will not be absolutely cold, it might serve for practical purposes. But perhaps the final solution will be found in some device which operates by electronic bombardment of some sort of screen or substance, which thru this bombardment will become intensely luminous. In other words, a device working on the principle of the well-known spurious light.

Such a device would consume an extraordinarily small amount of current, and would constitute an ideal source of cold light.

H. Gernsback

The ELECTRICAL EXPERIMENTER is for sale at all newsstands in the United States and Canada, also at subscription, 37 Avenue de l’opera, Paris.
'LEARN BY DOING'

The Only Way to Learn Electricity

It doesn't matter whether you are under twenty or over fifty; you can be trained in a short time to take a guiding hand in the World's most important industry.

The new Law compels men to follow only useful occupations—and every branch of electrical work is not only useful work but is most important.

If you want to learn a line of work that is interesting as well as remunerative—a light work easily learned that pays men of ordinary ability fifty dollars and upward a week—become an electrical practitioner.

Billions of dollars' worth of electrical equipment is being made and installed as quickly as possible. Why not learn this greatest and newest business—and share in the great profits? Electrical industry will continue to flourish when many other trades will be out of date.

If you have been following non-essential occupations, NOW IS THE TIME to learn something worth while. Hundreds of men have made successful fresh starts in life by spending a few months at the N. Y. Electrical School. You don't have to study from books in this school; you learn the many branches of electrical trades by using TOOLS and EQUIPMENT. The course may be finished in a short time at low cost. Whatever your age or position your condition can be improved and your country served to the best advantage by taking up the profession of Applied Electricity. Visit the School any day or evening and talk over matters. On request, a 68-page illustrated catalog will be sent FREE to you.

New York Electrical School

City of Ham Fired With Electric Bombs

The City of Ham was fired instantaneously by the crafty Germans after they had evacuated it, by means of electric incendiary bombs ignited by an electric current sent thru a network of wires from a point several miles away. The insert diagram at the left shows how the dastardly and wanton trick was accomplished by the throw of a switch.

The City of Ham—The French city of that name recently recaptured from the Germans, was set on fire by an elaborate system of electric incendiary bombs, all of which were placed throughout the various buildings with proverbial Hun thoroughness, which, when the psychological moment had arrived, were ablaze in an apparently natural manner; just as if the Allied shell fire had done the awful work. But the trick was not pulled off so smoothly—for we have the evidence in this case of some of the populace who managed to hide in cellars and other places of shelter of just what happened to Ham, once peaceful and happy, and birth-place of a well-known French electrician—Athanase Peltier—who discovered the remarkable electrical fact, that if a current is past thru a junction formed between bismuth and antimony, then the junction is either heated or cooled, depending upon the direction of flow of current thru the junction. This phenomenon is called in his honor, the "Peltier Effect".

Humanity is thankful for this additional information in the already mountainous pile of evidence against the boche, to one—Walter Duranty, a New York war correspondent of the New York Times, who was with the French army when they captured the still burning city. Mr. Duranty reports:

"For pure wantonness of destruction, Ham offers an example that even the Germans will find it hard to beat. It was a non-

all exploded simultaneously by an enemy officer located several miles away. Perhaps the crafty boche engineers thought that by wiring up the town in this way, and by driving out the inhabitants when the troops retreated, they could set the buildings..."
FRENCH ALPINE TROOPS CARRY BATTERY SEARCHLIGHT.

The electric searchlight has found more extensive use in the present war than in any previous conflict, owing to the fact that it has been improved and developed so that it has become a truly invaluable adjunct to all military and naval maneuvers, both for the purpose of illumination as well as for signaling. Small but powerful electric searchlights have been used successfully by the Allied armies for signaling in broad daylight, as was described some time ago in the Electrical Experimenter.

The present photograph shows a group of French soldiers—Chasseurs d’Alplne—sensing signals with a portable electric searchlight which can be held by one man. As those who have anything to do with automobiles will at once perceive, such a searchlight does not require a very large or extremely high candle-power lamp bulb, providing the lamp itself is fitted with a high grade parabolic silvered-glass reflector. Thus it is we find, that this member of the renowned “Blue Devils” is carrying the battery for operating the searchlight on his back, while he holds the searchlight projector itself on his breast.

Each of the mouths of a simple shutter arrangement fitted on these searchlights, when they are

military act of vandalism. Chauny street, leading to the market place, was piled high with the wreckage of fallen walls, and at the entrance to the square a group of pollux were risking their lives in clearing the outlook. A couple of houses whose glowing beams still crackled into flame at each gust of wind and whose side walls were bound to fall at any minute.

And my thought turned to that French woman who had lived in Ham before the Germans fired it, and who had hidden in a cellar while the cannon balls fell from the sky.

“Ham,” said a woman, “was destroyed methodically by fires simultaneously started in every quarter by electric devices. Nearly a month ago we noticed the hobs had begun fixing up wires in all directions, and we commented on the strangeness of such installation at a time when everything else pointed to a German retreat. It did our heart good to see the streams of guns, the material, and the shattered, dispirited troops that fled, pouring backward through Ham for the last few weeks.

“As time past the hobs steadily continued their preparations for departure, removing everything of furniture, and, indeed, everything of any value. But the wiring parties continued their work all the more busily.

“Last Wednesday we had the key to the enigma. That morning the French guns were very near and a few shells fell close. At noon, the officials issued orders to all civilians to evacuate the town. There were only about fifty inhabitants here, and perhaps twice that number of French and Allied soldiers in the boche press gangs. Some fifteen of us and six boys managed to hide in the cellars. I believe all save one or two are now safely accounted for.

“The next, at night, on Wednesday to Thursday we heard a sudden outbreak of small explosions all around. At first we thought there was grenade fighting in the street, as the noise was not loud enough for shells or air bombs. Before dawn my father stole cautiously out. The whole town was ablaze above our heads, but our house did not catch fire until we were able to leave it.

“The boche wires had been connected with incendiary bombs which were fired simultaneously from a central electric control. Ham burned furiously all Thursday and Friday. On Saturday morning the fire was dangerously close, and we left the cellar, to meet French soldiers, who had advanced and taken the town, shortly afterward.

“Our illustration herewith shows the scheme of carrying out such a dastardly deed. The incendiary bombs are connected up in series in circuit groups as here outlined, these groups being finally all connected to a single circuit leading to a central switch-board several miles away. At the closing of a switch the boche thus blasted out the only hope the peaceful inhabitants might have entertained of saving at least their homes and furniture.

GERMANS USE NEW AIRPLANE PARACHUTES FOR AViators

American Headquarters in France, Sept. 20. (Reuter)—Patrols report having encountered an entirely new type of enemy airplane, designed especially to make it easy to maneuver. They also report that the Germans are adopting the parachute as a means of escape from damaged planes.

Did you note the full purport of the last statement? Also, do you remember reading the timely article, “Is the airplane practice actual?” in the October number of the Electrical Experimenter? If you do, at least, we hope those who should be interested in such a life-saving device digested the logic the logic the logic in the paragraph who is a “flier” and, therefore, knows whereof he speaks. Yes, the report above cited looks good.

But, asks the reader, why do we not have such safety attachments provided for America’s birds? As usual the Germans have taken this idea, which had been tried out several years ago in France and the United States, and developed it to the stage of practicability. The reports from correspondents at the front have mentioned the Germans’ set forth by a man who is a “flier” and, therefore, knows whereof he speaks.

Finally, friends, listen to the clarion voice of the official bulletin, the “Anber of Aeroplane Improvement,” issued by the Naval Consulting Board. On airplane parachutes it says, “Those, considered as a safety device, ARE NOT DESIRED as a factor in the equipment of military airplanes. No entirely satisfactory disengaging device has yet been devised. To date, parachutes may presumably play some part in civil aeronautics and under peace conditions, but under existing military conditions they are not considered a necessary or desirable encumbrance.”

AMERICAN SPUN GLASS NOW IN ENDLESS LENGTHS.

In Venice, for many years, the art of glass spinning was fostered, till city became known for the great beauty of the ornamental objects which it put on the market. There have always been shortcomings in the work, due to the fact that glass thread could be spun only to the length of the circumference of the wheel on which it was wound, and this was never more than eighteen feet.

This difficulty has been overcome by an American Manufacturer, who can make spun glass thread in any lengths, and put it on spools as is done with ordinary threads. This enables manufacturers to make products to be made, that could not be made before. The spun glass can be made in all colors, giving a world of brilliancy.
